# Chemical (& Metallurgical) Engineering

A Semi-monthly Technical Newspaper,  
Being the Incorporation of  
Electrochemical and Metallurgical Industry  
and Iron and Steel Magazine

---

Volume XIX

*From July 1 to December 15, 1918*

---

*436844*  
*3. 7. 45*

NEW YORK  
McGRAW-HILL COMPANY, Inc.

# INDEX VOLUME XIX

## GENERAL ALPHABETICAL INDEX

Entries from the Synopsis of Periodical Literature are indicated by S. (Synopsis); from the Analysis of Current Electrochemical, Chemical and Metallurgical United States Patents by P. (Patents).

### A

|                                                                                                             |                    |
|-------------------------------------------------------------------------------------------------------------|--------------------|
| Abrasive, Increased production of artificial                                                                | 673                |
| Acetic acid and acetone, Industrial developments relating to the manufacture of Hibbert                     | 397                |
| —Made in Germany and Switzerland from calcium carbide                                                       | 399                |
| —War demand                                                                                                 | 399                |
| Acetone and acetic acid, Industrial developments relating to the manufacture of Hibbert                     | 397                |
| —For explosives                                                                                             | 399                |
| —War demand                                                                                                 | 399                |
| Acetyl cellulose, Lindsey (P.)                                                                              | 153                |
| Acids (See specific head)                                                                                   |                    |
| Acid, Concentrating, Process and apparatus for Hechenbleikner (P.)                                          | 43                 |
| Molecular, Recovery for steel mills, Brown                                                                  | 274                |
| —Lynna                                                                                                      | 169                |
| —Suspended TNT from                                                                                         | 274                |
| —Sulphuric, Excess in Britain                                                                               | 683                |
| —Sulphuric, nitric and mixed, Station                                                                       | 177                |
| Acids                                                                                                       |                    |
| —Charts for making mixed acids                                                                              | 820                |
| —Graphic method for fortification of the spent acids used in making nitrating mixed acids, Lopez and Seaman | 816                |
| Address to Society of Chemical Industry, Sholes                                                             | 704                |
| Aéroplane construction, Metallurgy and heat treatment of metals used in, Grotts, 121, 191, 241              |                    |
| Aéroplane fitting investigation                                                                             | 315                |
| Aéroplane parts, Typical examples of investigations                                                         | 127                |
| Activation, Calculation of extraction in continuous, Ham and Coe                                            | 603                |
| Aircraft work, Doping in                                                                                    | 595                |
| Air distribution in regenerative checkerwork, Huhnel (P.)                                                   | 45                 |
| Air Reduction Co., Sidlight on exposition                                                                   | 406                |
| Ajax-Wyatt vertical-rod induction furnace                                                                   | 391                |
| Ajo, Excavating tallines, Moeller                                                                           | 284                |
| Albertite and oil and paper shales, Simpson                                                                 | 119                |
| Alcohol                                                                                                     | 66                 |
| —As a source                                                                                                | 505                |
| —Butyl, War demand                                                                                          | 399                |
| —Ethyl, Wood waste as a source                                                                              | 506                |
| —Tomlinson                                                                                                  | 552                |
| —From sulphite waste liquors, McKee (S.)                                                                    | 67                 |
| —In the arts and industries, Leslie                                                                         | 506                |
| —Made in Germany and Switzerland from calcium carbide                                                       | 399                |
| —Miscellaneous uses                                                                                         | 507                |
| —Production of denatured                                                                                    | 506                |
| —Review of uses                                                                                             | 506                |
| —Use as a fuel                                                                                              | 506                |
| —Wood for motor purposes                                                                                    | 89                 |
| Allen Property Custodian probes ownership of chemical concerns                                              | 128                |
| Allen Property Custodian seizes Heyden Chemical Works                                                       | 177                |
| Allen property custodian seizes metal concerns                                                              | 117                |
| Alkali, Manufacture of McElroy, (P.)                                                                        | 152                |
| ALLOYS                                                                                                      |                    |
| —Aluminum and its light, Merica                                                                             | 135, 200, 320, 587 |
| —Bibliography                                                                                               | 729                |
| —Aluminum Constitution and properties with copper, iron, manganese, nickel, silver and zinc                 | 329                |
| —Aluminum, Equilibrium diagrams                                                                             | 587                |
| —Aluminum Tests of rolled binary                                                                            | 588                |
| —Perrin, Rhodes (P.)                                                                                        | 504                |
| —Perrin, Rhodes (P.)                                                                                        | 514                |
| —Perrins, Oxidized gases in, Allen and Darlington (S.)                                                      | 42                 |
| —Pie electric resistance elements, Driver (P.)                                                              | 200                |
| —Imports of ferronia                                                                                        | 774                |
| —Magnesium, Alloys, Aircraft (S.)                                                                           | 774                |
| —Pyrophoric-alloy industry, American Hirsch                                                                 | 510                |
| —Tensile properties of an aluminum-copper alloy                                                             | 330                |
| —Tensile properties of aluminum-copper-manganese alloys                                                     | 331                |
| —Tensile properties of aluminum-copper-nickel alloys                                                        | 331                |
| —Tensile properties of cast aluminum-copper-manganese alloys                                                | 330                |

|                                                                                            |          |
|--------------------------------------------------------------------------------------------|----------|
| ALLOYS—Continued:                                                                          |          |
| —Tensile properties of No. 12 casting                                                      | 589      |
| —Tensile properties of zinc-aluminum alloys                                                | 334      |
| —Uses of magnesium in                                                                      | 624      |
| —Alscer, Sylvine deposit in                                                                | 438      |
| —Aluminum, Pure, Front, Spence and Llewellyn, (P.)                                         | 779      |
| —Aluminates from alunit, Hershman, (P.)                                                    | 778      |
| ALUMINUM                                                                                   |          |
| —Its light alloys, Merica, 135, 200, 320, 587                                              | 635      |
| —Bibliography                                                                              | 729      |
| —Alloys, Constitution and properties with copper, iron, manganese, nickel, silver and zinc | 329      |
| —Alloys, Equilibrium diagrams                                                              | 587      |
| —Alloys, Tests of rolled binary                                                            | 588      |
| —Chemical properties                                                                       | 135      |

### Ourselves

FOUR times within the history of this journal we have injected a personal note into the editorial columns. The first occasion was when we introduced ourselves, nearly sixteen years ago. Twice after that we explained the successive changes in name which the journal underwent, and finally in 1912 we celebrated the tenth anniversary "of an insurgent engineering journal." Looking back over the record as it has been written in eighteen volumes, we may be pardoned if we indulge just a moment's gratification over the unflinching approval which our readers have so freely and genuinely extended as we have developed in the passing years. Truly, our readers have made possible by their splendid support whatever of achievement may be recorded in our volumes.

From the beginning this journal had a field that was not covered by any other similar publication. Unhampered by precedent and encouraged by a wonderfully friendly reception, we found it comparatively easy and delightful to break new trails. Always we have kept in mind the needs of the industry which we served, and whenever expansion or change seemed appropriate in the interest of better service we have never hesitated to make the effort to meet the need. Successful technical journalism requires a recognition of industrial trend and adaptability to changing conditions. Given these elements internally and the support of the profession from the outside and the result is inevitable. It must now be quite evident to any observer of current industrial development what we foresaw several years ago, namely, that chemical engineering is playing the dominant rôle of the day. Our country stands on the threshold of a marvelous development which has its basis in applied chemistry. There is scarcely an industry of any magnitude or importance that is without its chemical phase, and we are but beginning to appreciate the value of chemical control. Due to the stimulus of war we have suddenly become a chemical nation, investing millions in chemical manufacturing both on government and private account, and staking the future industrial independence of the country on the chemist and engineer.

It is under these favorable auspices, which we anticipated when we began semi-monthly publication several years ago, that CHEMICAL AND METALLURGICAL ENGINEERING now greets old friends with a revised and more appropriate name. There is fitness and proportion in all things—even names—notwithstanding the implication to the contrary in the classic query of the poet. Today's name would not have fitted the pioneer days of electrochemistry when this journal was launched, nor would *Electrochemical Industry* fitly indicate the broad field of

chemistry applied to industry and ore treatment which characterizes our field today. Further, as the metallurgist's art has progressed from rule-of-thumb to scientific standards, chemistry has been the underlying factor in the change. Metallurgy, therefore, has become a great branch of chemistry applied to the treatment of ores and metals—one great phase of our chemical industry. And so, with confidence in the logical nature of the change we have made, and feeling assured of the approval of our friends in this step in the evolution of a live, independent exponent of the chemical and metallurgical industries, we enter upon a new volume with a new sense of responsibility. Our house is now in order. We espouse the cause of the chemical engineer, the metallurgical engineer, and of those close relatives, not hyphenated, who are differentiated by the prefix "electro." We abandon no phase of the industry that has been included in our past evolution. There will be no diminution in our attention to electrochemistry and electrometallurgy. The treatment of ferrous, non-ferrous, precious and base metals and ores will have our interest as in the past, and the rapidly expanding chemical industry will be fitly served as becomes so important a factor in our national life.

### Speaking of Lead, Who Pays the Freight?

FIFTY years ago lead was cheap because it came from easily worked bonanza deposits. Since then the upward tendency due to the steady decline in grade of ore and increase in cost of labor has been counterbalanced by improvements in mining and metallurgical methods, together with decrease in freight rates. Indeed, the last item, freight, is so important to Middle Western and Western producers that it would be profitable to consider the effect of Mr. McAdoo's recent revision of rates. The increase amounts to 25 per cent on most commodities, ranging upward on essentials like coal, coke, flux and ore to a probable maximum of 55 per cent on bullion. With such unexpected jumps in the price of transportation, the custom smelter who contracted several years ago to treat ore at a price based on current and expected costs at that date is left with the alternatives of negotiating for a revision of the payment schedule, shutting down, or tumbling into bankruptcy.

The purely custom smelter or refinery operates under entirely different conditions from one which treats its own ores. The latter's deficit on a rising market may easily be swallowed by the handsome profit of the producing and selling departments. The custom smelter, on the other hand, is something like a salaried man if it operates on a "cost plus" schedule; in effect it then works for the miner, being but one of a train of related industries necessary to take lead from underground and put it into the plumber's pot. The total cost of the train must not only be less than the selling price of the metal, but the miner must get a share sufficient to pay for the delivery of the ore to the smelter, who in turn must receive a portion necessary to load the pig on cars. Lastly, the refiner's income at the least must balance his cost of putting usable metal on the market.

The production of lead is a field particularly well suited to study the effects of inflated prices. For years the price has fluctuated within such narrow limits that mutual relations between the various parties to the pro-

duction were well stabilized, and it had become almost a common saw that "Four cents is a good price for lead." On this basis the average of 4.3 cents for the decade ending with the war evidently provided a comfortable, perhaps more than comfortable, share for miner, smelter and refiner, with somewhat the following partition:

|          | Cents |
|----------|-------|
| Mining   | 1.4   |
| Smelting | 1.8   |
| Refining | 1.1   |
| Total    | 4.3   |

It will be noted in passing that these approximately correct figures correspond to conditions in those regions feeding the Colorado and Utah smelting centers. Most of these ores, of course, carry other valuable metals than lead, but the entire cost of smelting is assessed against the average lead content. This gives a fictitiously low return to the miner for his lead, but his receipts are augmented by the values of gold, silver, copper and iron. The case has thus been simplified for the argument which follows, since the wartime appreciation in market value of silver and copper has been equal to or greater than that of lead. "Mining" is thought of as including mining, development, amortization, freight and all other expenses incidental to delivering the ore to the smelter. "Smelting" includes the entire cost of recovering the base bullion, while the item "refining" covers freight on bullion and selling costs as well.

Since the war the price of everything has soared. In an inquiry in the Salt Lake region it was found that labor is receiving 50 per cent more now, for a considerably less efficient performance. Supplies have increased 35 per cent, coal 30 per cent and coke 50 per cent. On this basis the statement freely repeated that production costs have increased two-thirds in the last four years appears somewhat exaggerated when applied to the lead-smelting region; possibly an average increase of 50 per cent would represent the costs ruling for the first half of 1918. Therefore, in order that the operations may now proceed as comfortably as before, the new apportionment would approximate

|          | Cents |
|----------|-------|
| Mining   | 2.1   |
| Smelting | 2.7   |
| Refining | 1.6   |
| Total    | 6.4   |

The market was about 6.8 cents during this time, the surplus 0.4 cents going generally to the miner, who thus seems to be better taken care of than his partners. Indeed, it is unquestionable that the two latter have not increased their income proportionately to their costs, since so many old contracts are still in effect. In other words, the adjustment of contracts will lag far behind, while the ore shipments closely hug the rising markets.

But assuming for the instant that each has revenue enough to enable him to carry on his share of the work, now comes an increase in freight rates, bad enough in itself, but scaling all prices upward to an even greater extent. Carriage on bullion alone is increased 0.3 cents per pound. The smelter is hard hit on account of its

large requirements of flux, coal and coke. The miner weeps over his ore freights. An estimated reapportionment of expense would now be

|         | Cents |             |
|---------|-------|-------------|
| Miner   | 2.1   | + 0.2 = 2.3 |
| Smelter | 2.7   | + 0.3 = 3.0 |
| Refiner | 1.6   | + 0.4 = 2.0 |
|         | —     |             |
| Total   |       | 7.3         |

It is only another instance of the unending cycle: Up go wages, up go butter and eggs. Up go butter and eggs, up go wages. This much is plain, however: producing lead on a 7-cent market in 1918 is not as good a business proposition as on a 4-cent market in 1914. And when the price of lead exceeds the cost of production, as it will sooner or later by the operation of natural laws or by governmental price-fixing, the three partners in the business of producing lead must mutually revise their agreements so that each can continue to perform his indispensable functions. The mining company, for instance, can easily see the folly of insisting upon the continuance of a contract which will shut down the smelter, for he evidently could find no other present outlet for his ore on the old basis. On the other hand, a smelter with a sliding-scale contract which pinches the small producer should not strangle this output, even if small. Fair-minded men realize that the violent fluctuation of supposedly stabilized transportation is one of the things beyond control which invalidate price agreements; patriots subscribe to the motto, "Produce more, consume less"; and common sense indicates that galena is no good for making shrapnel bullets.

#### On the Price of Gold and Other Things

THE gold producer is between the devil of leaner ore and the deep blue sea of fatter commodity and labor prices. The before mentioned devil has kept the world's gold output practically stationary for the last ten years, and strenuous efforts to lower extraction costs by improved mining and metallurgical management have been overwhelmed by a tidal-wave of war prices.

Suppose you had revised your boiler room practice and equipment with much care and had finally increased the overall efficiency by some fifteen per cent. After looking over the results with considerable complacency you receive a letter one morning from your coal contractor saying that thereafter the price of your fuel will be the \$2.50 allowed by administrative action instead of the \$1.00 called for by your contract. Then you would feel as the gold miner feels.

The copper producer is in a different boat. He had cannily taken advantage of the present style in price-fixing and can point out that the increased cost of living demands a higher wage. For be it understood that the law (if it be a law) of supply and demand is distinctly out of date; Mother Grundy has whispered that a ruffian called Mars has spiked its guns, so that the time-honored statute can be winked at with impunity.

Time was when the impression was abroad that the more a man produced the better he should be paid, that the more efficiently a business was conducted the better should be the profits. Maximum production with the minimum expenditure seemed the ideal which would

provide amply for the comfort of great and small. But apparently we were all wrong—now-a-days wages are fixed by the cost of living, men and industries are paid according to what they spend, the tradesmen get all they can and let the hindmost look out for himself. Truly a comfortable creed if you are some distance from the hindmost, but a rule of conduct not calculated to cause soul-searching as to whether one is doing the best that is in him, or getting the best out of his tools.

Fortunately, there is a tacit agreement that this new philosophy is spurious and results in a vicious cycle of increasing prices, for all of us, through our government, have agreed to tax the war excess profits, proceeding on the theory that no one should grow fat on blood money. Right here is where the gold miner feels aggrieved. Theoretically, war taxes are imposts on excessive income returned from the inflated prices attending this cataclysm. Everyone can and does charge more for his produce than he could before, *except* the gold miner. The price of his yellow metal was established internationally long before the present price-fixing program was imagined; but unfortunately the more fundamental relationship between an ounce of gold and a day of labor was not recognized. Consequently the price of gold actually has dropped through its inability to purchase the old amount of other necessary products of man's labor. Since war prices have brought only a decrease in net revenue to the gold miner, his claim for exemption from war-profit taxation is well founded. It will probably fall on deaf ears, however, since to the ordinary run of mankind mining is a speculative enterprise rather than a foundation stone of industry.

The ultimate relationship of the value of gold and of all other things is somewhat as follows: If a country needs a thing, such as it does gold, and needs it badly, its citizens set themselves about getting it. If it exists, it can be had for a price. But the price paid to get it must not be greater than that which it in turn will buy. Therefore, as long as gold is to be the monetary standard, its value must fix the maximum limit to the price of labor and commodities. The spectacle of a stagnating gold production, while painful to the gold miner, is a welcome indication that, taken in a large way, the crest of high prices has been reached; a halt must be called else passing time will dangerously inflate an already top-heavy financial structure.

#### Devil-Hounds and Hounding the Devil

EVERY red-blooded unhyphenated American must have rejoiced recently at the published accounts of the performance of our marines when put to the supreme test in battle. Widely advertised in recruiting campaigns as "the first to fight," they ran true to form and showed that they were the last in the fight as well. Report has it that the enemy characterized them as *teufelhunde* after his first contact with them, but we rather incline to the artist's idea as expressed in the colored supplement to this issue, and agree with him that our marines are engaged in the laudable pursuit of hounding the devil. We suggest to our readers and subscribers that this supplement may be made to serve a useful and patriotic purpose if posted in the office or plant where the artist's inspiration may be transmitted to all.

## Meeting of the American Institute of Chemical Engineers

Important War-Time Convention Well Attended by Members from Distant States—  
Exceptional Opportunities Afforded to Visit Pulp, Paper and  
Chemical Plants of the Brown Company

THE tenth semi-annual meeting of the American Institute of Chemical Engineers was held June 19-22 at Gorham, N. H., which is the nearest village to the summit of Mount Washington—16 miles by carriage and automobile road. Gorham is surrounded by high mountains, there being twelve peaks within an eight-mile radius, the average height of which is more than 5000 feet. Mount Adams, as seen from Gorham, is the highest rise of land of its kind east

above which it towers to the height of 4937 feet; while Mount Washington rises but 4722 ft. above Fabyans and Bretton Woods, and 4661 feet above the Glen."

### WELCOMED TO NEW HAMPSHIRE

On the arrival of the Institute Wednesday forenoon MAYOR GEO. F. RICH met the organization at the Berlin City Hall and turned over the keys of the City. MR. JOHN HULAN spoke eloquently in appreciation of the

18. T. R. Wagner

19. J. C. Olsen, Secretary  
20. W. P. Mason  
21. L. D. Vorce  
22. A. C. Langmuir  
23. W. B. Campbell  
24. E. C. Holton

of the Mississippi river. Sweetsir's Guide Book says: "Mount Adams, as seen from a point on the road about one and one-half miles beyond the village, is the highest elevation which we can look at in New England from any point within a few miles of the base. Indeed, it is the highest point of land overlooking a station near the base that can be seen east of the Mississippi. The peak of Mount Adams (5805 ft. high) is about seven miles from the point before mentioned (868 ft. high).

honor of entertaining such a distinguished organization and informed the members that the Chamber of Commerce had arranged with citizens to furnish sufficient automobiles to carry the Institute to and fro. MR. O. B. BROWN spoke at the Grotto after lunch, where he told of the transition of the saw mill, starting in 1846 with the enormous mill-waste fires, through a period of forty-five years, when the sulphite wood pulp process was finally developed about 1888. Many ingenious ways of

Power Plant

Cell House

Chemical Plants

ELECTROLYTIC AND CHEMICAL PLANTS OF THE BROWN CO.

getting laths, shingles, etc., from normally unfit slabs were developed by saw-mill engineers, but nevertheless thousands of dollars worth of material was wasted weekly. In Michigan the mill people turned to chemistry and put up brine evaporators and Saginaw became the Salt City. The pulp process was the contribution of the chemist in the spruce belt, by which not only the waste was conserved, but thousand of square miles of small timber, practically valueless as it stood on the cut-over hills, was soon made a precious harvest crop. MR. BROWN did not speak at length, but his actions during

ladies saw this famous section of New England better than the chauffeured tourist ever did.

#### THE BROWN MILLS, BERLIN, N. H.

The Institute chose Gorham, so famous as a resort of the White Mountains, not merely because it offered its members a pleasant vacation from industrial pursuits, where they could discuss papers and become better acquainted through personal contact, but because from precedence as much as anything else, and certainly not from a lack of appreciation for the aesthetic; it has been

41. James P. V. Fagan  
42. Geo. A. Prochazka  
43. T. P. Summers  
44. William Garrigue  
45. H. G. Spear  
46. C. Bal Lilhne

the visit of the Institute expressed better than word the cordiality of his welcome.

#### LADIES WELL ENTERTAINED

The automobile service was the greatest treat in filling the program for ladies. The scenery of the White Mountains is an attraction that all ambitious travelers crave, and under the leadership of MRS. O. B. BROWN, MRS. HUGH K. MOORE and a dozen others the visiting

customary to hold these meetings at such points as offered visiting privileges to highly important chemical manufacturing plants. Fortunately, MR. HUGH K. MOORE, through his connections with The Brown Company, secured permission for his fellow members to visit their enormous lumber, pulp, paper, oil and chemical factories, which form the economic foundation of the thriving city of Berlin, but a few minutes ride by auto or trolley from Gorham.

### SULPHITE PULP MILLS

By the time one approaches these large mills, the sense of proportioning mass has been greatly augmented by the mountain scenery so that the 100,000-cord mountain-like wood pile at the supply yard does not excite even as much surprise as the ancient wooden horse of Troy. Nevertheless, the enormous wood-barking drums, the gang saws, the chippers and sorters, the extensive and various conveying appliances which deliver the wooden chips into any one of the long rows of digesters, the appliances for chemically controlling operations, and finally the sulphur burners and the acid ab-

sorption towers, bring emphasis to the statement that besides being the largest sulphite pulp mill in the world, this is certainly one of the greatest consumers of the products of nature. The magnitude of the operations may be summarized in the fact that if the daily wood supply of these mills were piled four feet high and four feet wide, it would extend over two miles in length.

solution is produced, which is concentrated, desalted and dehydrated to 76 per cent  $\text{Na}_2\text{O}$ , which is then put in the usual form of drum for shipment. Bearing in mind that the policy of this company is to utilize all by-products, one is not at all surprised to find a little brick furnace, heated to incandescence, up on the cell-house roof, which is believed to be the first commercial furnace burning hydrogen in chlorine gas as well as the only known hydrochloric acid plant that works without any attendants.

Having quantities of sulphur on hand for use in the sulphite mill, it was no more than natural that the sul-

RIVERSIDE MILL AND WOOD YARD OF THE BROWN CO.

phur chlorides should be made by burning sulphur with chlorine, also that wood charcoal and sulphur should be combined to carbon disulphide, and that from the above carbon tetrachloride and chloroform should follow in sequence. Medicinal chloroform is also made by the alcohol-bleaching powder method in tank-car quantities at the present time.

phur chlorides should be made by burning sulphur with chlorine, also that wood charcoal and sulphur should be combined to carbon disulphide, and that from the above carbon tetrachloride and chloroform should follow in sequence. Medicinal chloroform is also made by the alcohol-bleaching powder method in tank-car quantities at the present time.

### THE CASCADE PAPER MILL

Not all of the pulp is sold as such by the company, the Cascade Mill shipping about 200 tons of paper daily. In the operation of this plant there are employed 800 persons receiving about \$11,000 per week; 23,000 horsepower is generated, of which about 8000 is electric and 7000 each hydraulic and steam; seventeen 400-hp. boilers burn 125 tons of coal daily in furnishing steam. Four immense paper machines each produce 48 tons of news paper daily, which is 164 inches wide and runs through the machine at the rate of 600 ft. per minute.

### THE CHEMICAL DEPARTMENT

Years ago the company bought its bleaching powder from England, but for some time has operated its own electrolytic cells of a design by MESSRS. MOORE and ALLEN. An extremely chlorate-free sodium hydroxide

### THE OIL-HYDROGENATION DEPARTMENT

DR. CARLETON ELLIS has written a book on this subject so that the interested reader may find elaborate published accounts of how oils in the presence of nickel will absorb hydrogen gas and change their properties by becoming solids at ordinary temperatures. Pure peanut oil is used in the Brown plant. The features of the process are the thorough manner in which the reagents are brought into contact, the moderate temperatures and the reaction speed, so that the fat is soon on the chill rolls, then into the "Kream Krisp" container. The art of the oil refiner is to purify this carbon-hydrogen-oxygen compound—oil—furnished us by nature. With the exception of adding hydrogen to the product as in the above process, all oil refining consists of removing foreign products by washing out fatty acids, etc., with dilute alkali, removing soaps, colors, etc., with fuller's

CASCADE PAPER MILLS OF THE BROWN CO.

earth, and steam-distilling all odorous volatile oils and moisture from the finished product.

#### PHOTOGRAPHIC DEPARTMENT

Of the many technical laboratories special mention should be made of the photographic department. MR. JOHN H. GRAFF has developed many applications of color photography in technical analysis of pulp from various woods. Very beautiful artistic pictures of chocolate coatings, etc., were shown which approached the actual color and texture of the original specimens. There is promise that the physical qualities of oils and fats will eventually be studied by this method similar

Fine club houses for young women and men have been erected; but more unusual and greater than all is the "Show," which stimulates good fellowship better than any other activity and provides mental training for scores of participants.

The members of the Institute agreed that they had never witnessed better amateur talent than by the Burgess Minstrels in the presentation of "A Joyous Jumble of Junk" in three acts entitled "Somewhere in America." MR. HERBERT SPEAR proved to be as much at home leading a company of ninety as though he were by profession a "Comical Engineer" instead of chemical. DENNIS CAMPBELL and LORA ROWELL presented the rural

BURGESS SULPHITE PULP MILL OF THE BROWN CO.

to those of steel and alloys in metallography. Mr. Graff has a blue center on a red field through which he filters the microscope light, so that the finest differentiation between the planes of cleavage, faces, etc., is obtained in the photograph. His photos of jewels, such as diamonds, are the best means known today for recording the true color effects as well as physical forms and thus give positive identification records.

The social welfare of the workers in the Brown Company has not been provided for on the seventh day alone.

act in refreshing manner. The "Six Smiling Scoundrels" were as capable as if they had seen service with Lew Dockstader himself. Of their acts, the kiddy kar worked extremely well and would take New York almost as well as the Daffodils did under the lead of Bessie McCoy. Of their riddles; the "Resemblance of a Slacker to a Lemon Pie" may be taken as an average. Some good ones were perpetrated on a few individual members of the Institute, but the "No Crust on Top and Yellow Inside" was left for each individual himself to

determine how far he had a right to stray from the kahki. DR. WESSON said that there was less than a third as much  $\text{CO}_2$  in the air at Berlin as in New York or Boston, which must account for the extra brilliance of the young ladies in the cast.

#### BANQUET AT THE MT. MADISON HOUSE

One hundred and four covers were laid at the tables which were set in the form of a large U. DR. MASON acted as toastmaster. MR. W. R. BROWN, who has

been built to regulate the current, etc., yet he did promise to furnish all those who came up into the woods a regular Brown welcome. DR. OLSEN gave the toast to the ladies, which was delivered in a manner typical of the genial Secretary of the Institute.

#### TRIP THROUGH THE MAINE WOODS

A heavy rain began Friday night which continued all day Saturday, but after voting on whether it was advisable to make the scheduled trip up through Thir-

OIL REFINERY AND HYDROGENATION PLANT OF THE BROWN CO.

charge of the timber operations of the company, made an address, and while he did not mention the fact that his department is really the largest manufacturing department of the whole company, where cellulose is manufactured by catalytic action of sunlight on  $\text{CO}_2$  in the leaf cells, where the water vapor from the Atlantic ocean is condensed on the mountain sides to keep the Androscogin flowing, and where storage reservoirs have

teen-mile woods to Errol Dam, so many members decided to go that the official meeting was transferred to the Lakewood Camps in spite of the weather.

Fourteen papers were read during the meeting, occupying ten hours time. Some of these will be printed in full or in abstract form in future issues of CHEMICAL AND METALLURGICAL ENGINEERING. Every minute of the trip was time enjoyably spent.

#### Government Restricts Location of New Industries

A policy has been adopted and made effective for preventing further increase in the volume of war orders and the number of establishments handling them in the area known as the congested manufacturing and transportation district. This district comprises the New England states; eastern and southern New York; Pennsylvania as far west as Williamsport and Altoona; all of New Jersey and Delaware; eastern Maryland, not including Baltimore.

Exceptions to this policy will be made only if unavoidable through inability otherwise to provide for war needs.

The congested district comprises those eastern states in which so large a proportion of war industries is located as to make it difficult to supply all with necessary raw material and fuel. This difficulty obtains because coal for those industries is

mined in the territory west of the Allegheny Mountains. It must be carried into this congested district by a limited number of railway lines and by ships from Hampton Roads and Baltimore.

The amount of coal, therefore, which can be transported into this congested area during any one season is limited, and is an entirely separate problem from the production of coal. However much coal is mined in western Pennsylvania, West Virginia and Ohio, only so much is available for this congested district as the railroads and ships can transport.

A careful analysis of the possible coal movement shows that the increased industrial activity in those eastern states has created a requirement for coal which exceeds the limit of possible transportation of coal, plus necessary materials for manufacture. A map of the congested and restricted district has been issued to all Government departments.

## James Douglas

**D**R. JAMES DOUGLAS, philanthropist, mining engineer, chairman of the board of directors of the Phelps, Dodge Corporation, died at his home in Spuyten Duyvil, near New York City, on June 25 in the eighty-first year of his age. He had been president of the corporation for many years until recently, when he resigned on account of failing health.

Dr. Douglas gave away large sums of money for educational and charitable purposes, but his most noteworthy gift was made to the General Memorial Hospital of New York of 3.75 grams of radium, value \$375,000, to be used in cancer-therapy. This radium represented one-half of the output of the National Radium Institute produced by three years of work on carnotite ores in the West. Dr. Douglas was born at Quebec, Canada, Nov. 4, 1837. His father, Dr. James Douglas, Sr., was a surgeon of repute, and the first to introduce modern treatment of insanity into Lower Canada, as the founder of the Quebec Lunatic Asylum, in the management of which for some time his son James participated. James Douglas was educated in Canada, Germany and Scotland. He received the degree of A. B. at Queens University, Canada, studied medicine at Laval University and was professor of chemistry at Morrin College, Quebec. He acquired his first experience in mining and metallurgy through his connection with the Harvey Hill mines and other mining properties in Lower Canada and went to Phoenixville, Pa., in 1875, where he took charge of the metallurgical operations of the Chemical Copper Co., where he was first to refine on a commercial scale pure copper by the electrolytic method.

In 1880 Dr. Douglas first visited Arizona and saw the Copper Queen mine, and a year later, in the interest of the late William E. Dodge and the late D. Willis James of the old firm of Phelps, Dodge & Co., acquired copper claims in the Warren mining district, Arizona, and the copper mines at Morenci, Ariz. These claims in

1885 had become productive, and were absorbed into the Copper Queen Consolidated Mining Company, of which Dr. Douglas became president.

Later, the Detroit Copper Mining Co., Morenci, Ariz.; the Untied Globe mines, Globe, Ariz.; the Motezuma Copper Company, Nacozari, Sonora, Mexico; the Commercial Mining Co., Prescott, Ariz.; the Stag Cañon Fuel Company, Dawson, N. M.; and the Burro Mountain Copper Company, Tyrone, N. M., were acquired by companies of which Dr. Douglas was president and manager. In 1908 these properties were consolidated into the fifty million dollar corporation of Phelps, Dodge & Co., of which Dr. Douglas was president. The railroad building under Dr. Douglas's management, begun in the early eighties, continued to expand with the growth of the copper companies, and at the present time under the title of the El Paso & Southwestern Railroad Company, operates over one thousand miles of standard-gauge road.

Dr. Douglas was the author of a number of books, among which were "Canadian Independence," "Quebec in the Seventeenth Century," "New England and New France," "Journals and Reminiscences of James Douglas, Sr." He also wrote very many literary and technical articles, reports, addresses, and delivered many lectures, including a series of the Cantor lectures, before the Society of Arts, of London.

JAMES DOUGLAS

Dr. Douglas was twice president of the American Institute of Mining Engineers, was the recipient of the gold medal of the Institution of Mining and Metallurgy of London and in 1915 was awarded the John Fritz medal. In 1899 McGill University conferred on him the honorary degree of LL.D. In 1916 he was elected Chancellor of Queens University, his alma mater.

In 1860 Dr. Douglas married Miss Naomi Douglas, daughter of Capt. Walter Douglas, of Quebec; six children were born, of whom the following are now living: Major James S. Douglas, Watler Douglas, Miss Elizabeth Douglas and Mrs. Edith M. Douglas.

## Camphor Production and Imports

The supply of camphor will be governed by the ship cargo space available from Japan and necessary munition requirements. It is hoped that the short markets will stimulate synthetic investigations, as well as the development of this gum tree in the Americas. As is well known, pinene, the light distillate from turpentine, saturated with anhydrous hydrochloric acid gas at a low temperature, gives a solid gum product. This has been trade named artificial camphor and scientifically called pinene hydrochloride, both of which names are not well founded, the product having proven to be a camphene-chloride. As natural camphor is a ketone, the chlorine is

substituted with an hydroxyl radical, the product oxidized, and actual artificial camphor produced. Perhaps hydrofluoric acid would be better than hydrochloric, the fluorine being better removed by silica compounds and the entire reactions becoming more co-ordinated and complete.

The following are the camphor imports for March periods:

|           |               |
|-----------|---------------|
| 1918..... | 3,736,240 lb. |
| 1917..... | 7,099,423 lb. |
| 1916..... | 4,122,735 lb. |

## Our Expanding Dyestuff Industry

U. S. Tariff Commission Makes Preliminary Report on Census of Coal-Tar Products for 1917—Shows Production Exceeds Pre-War Imports—Value of Exports Exceeds Pre-War Imports

THE United States Tariff Commission announces the completion of its census of coal-tar products for 1917. This group of products includes not only the coal-tar dyes and the crude and intermediate materials required for their manufacture, but also all of the medicinal and photographic chemicals, explosives, synthetic resins, synthetic perfume materials, and flavors which are in any way derived from coal-tar products. There were produced in the United States (not inclusive of explosives and synthetic phenolic resins) 54,367,994 pounds of dyes and other finished products, which have a total value of \$68,711,228. The production of the materials known as intermediates amounted to 322,650,531 pounds, with a value of \$106,942,918. The annual production was reported for the following groups of products made in whole or in part from materials derived from coal tar: 45,977,246 pounds of dyes valued at \$57,796,027; 5,092,558 pounds of color lakes valued at \$2,764,064; 2,236,161 pounds of medicinal chemicals valued at \$5,600,237; 779,416 pounds of flavors valued at \$1,862,456; 263,068 pounds of photographic chemicals valued at \$602,281; and 19,545 pounds of perfume materials valued at \$125,960.

There were 81 establishments engaged in the manufacture of coal-tar dyes in 1917 and their production during that year was practically identical with the amounts annually imported before the war. The imports for the fiscal year 1914 amounted to 45,840,866 pounds and the production in the United States in 1917 was 45,977,246 pounds. However, an analysis of this total reveals that the domestic production, though equal in quantity to the preceding imports, differs in the relative amounts of the various classes of dyes. Only a small production was reported for indigo, and the alizarin and vat dyes derived from anthracene and carbazol—classes of dyes which include some of the best and fastest colors known to the textile trade. The United States produced only 2,166,887 pounds of these dyes in 1917; and the elimination of 1,876,787 pounds of extract made from imported indigo reduces the output of these dyes to less than three per cent of the pre-war imports. Dyes of this class are dutiable at 30 per cent in the Tariff Act of 1916. The lack of development in the remedied to a considerable extent in 1918, for a number

of firms have begun their manufacture and a large increase in production can clearly be foreseen.

In the classes of dyes which if imported would be manufacture of these particular dyes promises to be dutiable at 30 per cent plus five cents a pound, the American manufacturers have shown remarkable progress, producing 43,810,359 pounds at a total value of \$57,639,990. That this

represents something of an excess over the American needs is evidenced by the fact that during the fiscal year 1917, American-made dyes to the value of \$11,709,287 were exported to other countries. Thus the exports exceeded the pre-war imports in total value although not in tonnage nor in the variety of the dyes. The developments of the manufacture of intermediates is equally marked, for before the war almost all of these necessary materials were imported from Germany. The Tariff Commission finds that intermediates

### Value of 1917 Exports Exceeds 1914 Imports

|              |              |
|--------------|--------------|
| Imports 1914 | \$ 9,102,066 |
| Exports 1917 | 11,709,287   |

### Tonnage of 1917 Production Exceeds 1914 Imports

|                       |            |
|-----------------------|------------|
| Imports 1914, lb.     | 45,840,866 |
| Production, 1917, lb. | 45,977,246 |

### Production and Value, 1917

|                     | Pounds      | Value        |
|---------------------|-------------|--------------|
| Coal Tar Dyes       | 45,977,246  | \$57,796,027 |
| Color Lakes         | 5,092,558   | 2,764,064    |
| Medicinal Chemicals | 2,236,161   | 5,600,237    |
| Flavors             | 779,416     | 1,862,456    |
| Photo Chemicals     | 263,068     | 602,281      |
| Perfume Materials   | 19,545      | 125,960      |
| Total Dyes, etc.    | 54,367,994  | \$68,711,025 |
| Intermediates       | 322,650,531 | 106,942,918  |

were manufactured by 117 firms in 1917 and that the production amounted to 322,650,531 pounds valued at \$106,942,918. These figures, however, are somewhere misleading as there is inevitable duplication in the totals. It is well known that many of the intermediates are derived from other products of the same class. Thus starting with benzol the following succession of products is obtained: nitrobenzol, anilin, acetanilid, nitroacetanilid, and nitranlin. Each of these products had to be reported by the manufacturer and hence there has been some cumulative counting.

The totals for all of the coal-tar products will be published in the final report which may well be expected to offer accurate evidence on the progress of the American dyestuff industry.

### German Institute for Metallurgical Research

About a year ago a special research laboratory was planned to promote the progress of German metallurgy with a view to the exceedingly keen competition to be anticipated after the war. The location of the research institute will be in the Rhenish-Westphalian industrial region, and the considerable funds required for the construction and maintenance will be provided largely by the iron and steel industry, which probably will be most affected.

## U. S. Tariff Commission Holds Hearings on Tungsten at Denver

The meeting of the United States Tariff Commission was held in the District Court Room, Federal Building, at 10 a.m. June 17, to receive testimony from the producers of tungsten of Boulder County, Colorado, on the need of a tariff to protect their industry.

The Commission was represented by Mr. E. P. Costigan and by its Metallurgical Expert, Mr. Guy C. Riddell.

Among the operators presenting testimony were: Mr. Warren Bleecker, President of the Tungsten Products Company, Boulder. Mr. Harold Boericke of the Primos Chemical Company. Mr. William Loach of the Wolf-tung Mining Company. Mr. John A. McKenna of the Vasco Mining Company. Mr. John G. Clark of the Boulder Tungsten Production Company. Mr. Nelson Franklin of the Rare Metals Ore Company. Mr. William Coudrey of the Long Chance Mining Company. Mr. I. N. Bair, leaser on the Good Friday Mine. Mr. Edwin E. Chase, Mining Engineer of Denver. Mr. Emerson J. Short of the Union Mine and Development Company, Denver. Mr. Stoddard of the Black Metals Company, Boulder.

MR. WARREN F. BLEECKER presented a report signed by the operators of Boulder County through their Committee asking that they be given protection by a tariff which would raise the price of 60 per cent concentrate to \$30 to \$40 per unit.

The Boulder County Committee was of the opinion that the adequacy of American deposits for domestic needs is largely dependent upon the price and stability of the market. In 1917 there was produced in Boulder County from 2800 to 3000 tons of concentrates requiring the labor of approximately 750 men. At one time during the boom in 1915-1916 as many as 3000 men were directly employed in the tungsten industry in Boulder County, showing that an increase in the price causes very many more people to engage in the industry.

Mr. Bleecker then took up some of the metallurgical details of Boulder County practice, showing that an average recovery was 75 per cent, and that on the horn ores they only made 50 per cent recovery. He showed that due to the fine grind necessary to removing the gangue material there was a heavy slime loss, and stated that there was no new satisfactory process for slime recovery. He stated that whereas ferberite had always been considered the best material for the electric furnace manufacture of ferrotungsten, scheelite was now being used successfully and was commanding a premium for this work which formerly had been commanded by ferberite. He stated that the high phosphorus on the Boulder County concentrate compelled the refining process which was not necessary with scheelite. He felt that there has been much misinformation spread as to the impurity of foreign ores, as most of the foreign ores were as pure as our ore. He felt that a price of \$30 to \$40 per unit should be established for 60 per cent tungsten concentrate.

MR. NELSON FRANKLIN of the Rare Metals Ore Company gave some typical figures of actual expenditures in the production of 60 per cent concentrate from the mining operations of the Tip-Top Leasing Company and the Black Metals Mining Company. These were the only

### COST OF PRODUCING TUNGSTEN CONCENTRATE THE BLACK METAL MINES COMPANY STATEMENT OF PRODUCTION COST, 1917

| Total Expenditures                          | Production  |           | Units WO <sub>3</sub> | Cost Per Unit |
|---------------------------------------------|-------------|-----------|-----------------------|---------------|
|                                             | Tons        | Per Cent. |                       |               |

| Total Units Produced                        |             |           | 2 295                 |               |
| Less 20% loss in milling.....               |             |           | 0 459                 |               |
| Net units recovered.....                    |             |           | 1 836                 |               |
| Less 20% royalty to owners of property..... |             |           | 0 367                 |               |
| Net units recovered for sale by us.....     |             |           | 1 469 =               | \$19.82       |
| Hauling charges on 1,222 83 tons @ \$2.00 = |             |           | \$2,445 86            | 1 33          |
| Milling charges on 1,222 83 tons @ 6.00 =   |             |           | 7,336 98              | 3 99          |
| Total cost per unit produced.....           |             |           |                       | \$25.14       |

The royalty is based on the recovery in concentrates and owners of the properties under lease pay their proportion of the hauling and milling charges, hence these costs are divided by the net recovery in concentrates from the mill, whereas the net cost to us is based on the net recovery by us on our proportion of the recovery in concentrates.

| Our engineers estimate that we have 2,000 tons of ore developed, of an average grade of 1.10% WO <sub>3</sub> .                                       |              |
| 2,000 tons @ 1.10%.....                                                                                                                               | 2 200 units  |
| Less loss in milling 20%.....                                                                                                                         | 0 440 units  |
| Net units recovered.....                                                                                                                              | 1 760 units  |
| 15% royalty to owners' property.....                                                                                                                  | 0 264 units  |
| Net units recovered by us for sale.....                                                                                                               | 1 496 units  |
| Mining cost yet to extract ore 1,800 tons. \$4.00 per ton.....                                                                                        | \$7,200.00 = |
| Hauling charges on 2,000 tons @ \$4.00.....                                                                                                           | 8,000.00 =   |
| Milling 2,000 tons @ \$6.00.....                                                                                                                      | 12,000.00 =  |
| Total cost per unit produced.....                                                                                                                     | \$31.84      |

The royalty of 15% is based on the recovery in concentrates and the owner of the property has to pay his proportion of the hauling and milling charges, hence these costs are divided by the net recovery in concentrates from the mill, whereas the net cost to us is based on the net recovery by us on our proportion of the recovery in concentrates.

### COST OF MANUFACTURE FERROTUNGSTEN, FERRO ALLOY COMPANY, JUNE, 1917

\* Tungsten in residues credited at \$1.25 per lb. W, which was cost with 20% concentrate.

This cost statement includes all costs up to sale, packing, and shipment from plant. Adding these items gives cost f. o. b. New York:

|                                      |         |
|--------------------------------------|---------|
| f. o. b. plant, operating cost.....  | \$0.291 |
| f. o. b. N. Y., additional cost..... | 0.090   |
| Ore cost.....                        | 1.477   |

Total cost sold and delivered New York, per lb. W..... \$1.856

actual cost figures drawn from the ledger made public at the meeting, although other figures were given as confidential for the use of the Tariff Commission. Copy of these costs is presented herewith.

MR. EDWIN E. CHASE stated that the Good Friday Mine was under lease to I. N. Bair, and that although this mine had one of the best showings of tungsten in the district it could not operate at a profit with concentrate at \$22 to \$25 per unit. In reply to question from the Tariff Commission he stated that he didn't believe that the tungsten resources of Boulder County were by any means exhausted, but that the easily reached deposits were worked out.

MR. EMERSON J. SHORT produced figures attempting to show that all of the profit in tungsten operations was obtained by the mill-man and the ferrotungsten manufacturer. He claimed that the cost of the production of ferrotungsten for operating expenses, but not including the price of ore, was 14¢. per pound of W contained, and that the power cost was approximately 1¢. per pound of W contained. His figures on milling were much lower than those stated by others present.

MR. R. M. KEENEY of The Ferro Alloy Company produced actual cost figures on the manufacture of ferrotungsten showing a cost of about 38.1¢. per pound of W for ferrotungsten delivered in New York. These figures include the entire operating expense and express to New York. He also stated that the Ferro Alloy Company ceased its operations on the manufacture of ferrotungsten and converted its plant into a ferrochrome plant last July because of the fact that at that time tungsten concentrate went to \$27.50 per unit with ferrotungsten remaining from \$2.15 to \$2.25 per pound of contained tungsten. The concentrate cost, under these conditions, was \$2 per pound, which with an operating cost of 38¢. per pound made a total cost of \$2.38 per pound. These figures were corroborated by another producer present. A copy of the cost of the manufacture of ferrotungsten by the Ferro Alloy Company, June, 1917, is given herewith.

A representative of the Miners' Union from Nederland, Colorado, who was also a leaser, stated that the miners were not getting enough pay; that instead of a \$4 a day minimum they should get \$5 a day minimum. However, he said that, as a leaser, he could not afford to pay any higher wages as he had a very close margin of profit with present wages, and felt that the only way to get higher wages was to put the price of tungsten concentrate up to \$30 to \$35 per unit. He felt that rather than establish the price of concentrate on the basis of 60 per cent, some means should be taken to arrange a definite schedule for ores from 1½ up to 60 per cent, as he felt that the miners never knew what price they were going to get for concentrate until it was shipped to the mill and that the mill did not pay them a high enough price. Several present showed that the mill was paying all that it could afford to pay, but there was a general consensus of opinion that rather than establish a price of concentrate the price should be established on certain grades of ore so that the miner could look forward to a fixed price. Part of this testimony was considered by the Tariff Commission to be evidence more for the fixation of a price on tungsten rather than showing the need of a tariff to protect the producer of ore.

## Water-Power Committee Agrees on Bill

THE special committee appointed in the House of Representatives to consider all proposals for water-power legislation has completed its work and has agreed upon a bill which will be presented to Congress probably early in July. The bill is practically identical with what was known as the Administration Water Power Bill which was made the subject of hearings that have been previously reported<sup>1</sup>.

In its essential features the bill provides for a Federal Power Commission consisting of the Secretaries of War, Agriculture and the Interior. The President is to designate the chairman of the commission, which is to issue licenses for the development of water power projects, the term of the license to be not exceeding 50 years.

The original definition of net investment is retained. The bill also contains the original options regarding the disposition of the project at the end of the 50-year license period, and relating to the regulation of rates of service and character of securities.

A new provision was written into the bill requiring the licensee to maintain out of surplus earnings, if any, accumulated in excess of a specified rate of return upon the net investment, amortization reserves to be held until the termination of the license or applied periodically in reduction of the net investment. The license may provide that any balance or surplus earnings shall be used in reduction of rates and annually returned to the consumer.

## Steel Prices Fixed for Three Months

The President has approved the agreement made by the Price-Fixing Committee of the War Industries Board with the representatives of the iron ore, pig iron and steel interests, that the maximum prices now prevailing on iron ore, pig iron and iron and steel products be continued in effect for the three months ending September 30, 1918, with the following exceptions:

### 1. Lake Superior Iron ore:

Base prices of Lake Superior iron ore delivered to lower Lake ports are increased 45¢. per gross ton on and after July 1, 1918, subject to the following condition: These increased prices are based on the advances in rail freight rates effected June 25, 1918, and on the present lake rates and in the event of any increase or decrease in either rail or lake rates said prices shall be increased or decreased accordingly on all deliveries made during the continuance of such increased or decreased freight rates.

### 2. On and after July 1, 1918, the basing point for steel bars, shapes and plates will be Pittsburgh, Pa.

No new contracts calling for delivery of any of the above commodities or articles on or after Oct. 1, 1918, are to specify a price unless coupled with a clause making the price subject to revision by any authorized United States Government agency, so that all deliveries after that date shall not exceed the maximum price then in force, although ordered or contracted for in the meantime. It is expected that all manufacturers and producers will observe the maximum prices now fixed.

<sup>1</sup>This Journal, Vol. XVIII, No. 5, (Mar. 1, 1918, p. 225), *en. 6.* (Mar. 15, 1918, p. 286), No. 7, (Apr. 1, 1918, p. 339), No. 9, (May 1, 1918, p. 439), and No. 11, (June 1, 1918, p. 568).

## The President's Readjustment and Reconstruction Commission—II.

### Elaborate Preparations Already Made by England's Ministry of Reconstruction

BY WINGROVE BATHON

Washington Representative, McGraw-Hill Co., Inc.

THE previous article in this series suggested and urged the appointment by the President of the United States of a readjustment and reconstruction commission, to begin to deal now with vital problems in industry which will be presented after the war. It was pointed out that many other countries, notably Great Britain, have already begun to attempt to solve after-the-war problems. The personnel of a suitable commission, selected from the ranks of American industry, and of an advisory council, taken from the ranks of Government officials, to work with such a commission, was suggested in detail.

Some of the far-reaching work being done along this line by Great Britain is now presented as an evidence that it is necessary for American industry to begin now to prepare to solve after-the-war problems. This description of Great Britain's Ministry of Reconstruction is taken from the official reports to Parliament of the British War Cabinet, furnished to the writer for the purpose of this article by Arthur Willert, Secretary of the British War Mission at Washington. These reports are inclusive of the year 1917 and have just been sent to Washington.

#### BRITISH MINISTRY OF RECONSTRUCTION

After tracing the earlier stages of the Ministry of Reconstruction in Great Britain, before it was established by the New Ministries Act, in July, 1917, and when the agency of reconstruction consisted of a committee of Ministers of the Crown, the War Cabinet reported that it was found necessary to establish a Ministry of Reconstruction to continue for the duration of the war and for a period of two years, or less, after its conclusion. It was declared that a Prime Minister upon whose shoulders fell the responsibility for the conduct of the war could not personally assume a day-to-day responsibility for guiding the Reconstruction Committee's work. It was stated that the Government had throughout been aware that as the war continued, and its pressure upon every side of the national life increased, the intensity of the struggle in itself enhanced the importance of the reconstruction problems which had to be faced; and that Parliament and the country were not slow in realizing that there was coming into existence a series of questions of the utmost importance to which answers must be found, not after, but before, the conclusion of the war.

The functions of the Minister of Reconstruction then appointed and who assumed office in August, 1917, are defined as follows:

"To consider and advise upon the problems which may arise out of the present war and may have to be dealt with upon its termination, and for the purposes aforesaid to institute and conduct such inquiries, prepare such schemes, and make such recommendations as he sees fit; and the Minister of Reconstruction shall, for the purposes aforesaid, have such powers and duties of any

Government department or authority which have been conferred by or under any statute as His Majesty may by Order in Council authorize the Minister to exercise or perform concurrently with, or in consultation with, the Government department or authority concerned."

In other words, as was brought about during the debate which resulted in the creation of the Ministry, the Minister in charge does not exercise executive functions; he appoints committees; he initiates experiments; he frames schemes for action with a view to conditions after the war; his powers are not exclusive and do not shut out other departments; he assists the other departments, provides them with information and helps them "to build a bridge which will safely carry us over from war to peace conditions." The British Parliament found that the creation of a reconstruction agency was desirable because various government departments are approaching various problems in their own way, each drawing up reports or memoranda, and that what was needed was a co-ordinating element, not especially attached to the work or to the traditions of any one of the departments concerned. The Solicitor-General of Great Britain, speaking in debate, said that what was needed was a "comprehensive co-ordinating mind, a fresh mind, and at the same time an authoritative mind, who will bring together the several contributions of the various specialized departments."

#### BRANCHES OF THE BRITISH MINISTRY

The Ministry of Reconstruction was then formed. For the purposes of administration the department was divided into branches dealing respectively with Commerce and Production, including the supply of materials; with Finance, Shipping and Common Services; with Labor and Industrial Organization; with Rural Development; with the Machinery of Government (Central and Local); Health and Education; and with Housing and Internal Transport.

The Minister of Construction then appointed an Advisory Council, "representative of all the leading interests concerned in reconstruction, and it is his hope by consulting the Council freely and regularly to secure a representative consensus of opinion on any proposal which may be referred to him for advice or which may be initiated in the department." This Council is organized very much as the Pan American Financial Conference held in Washington at the beginning of the war was organized, and very much as the old War Industries Board of the Council of National Defense of the United States was organized. In other words, there are experts in each line named to serve the government representatives. The Council is divided into sections, just as the administration of the Ministry of Reconstruction is divided. It is stated that "the membership of the Council has been so arranged that in each section all the principal interests represented on the Council should find a place; thus, there are representatives of labor on the finance section as well as financiers; there are business men as well as agriculturists on the section dealing with agriculture; and so on."

The meetings of the sections of the Ministry and the Council are private, but it is known that they have already dealt with the standardization of railway equipment; the post-war rationing of industries; the establishment and functions of trade organizations; the or-

ganization of rural information centers; the establishment of industrial courts; house planning from the point of view of domestic economy; the future organization of voluntary women's work; and the conditions required for maintaining a supply of efficient agricultural labor.

#### WORK ALREADY ACCOMPLISHED BY DIFFERENT SECTIONS

The section dealing with commerce and production is investigating (1) the supply and control of raw materials after the war; (2) financial facilities for British commerce and industry after the war; (3) the preservation of industries which will play an essential part in reconstruction but are in extinction through failure of supplies of material or labor; (4) financial risks attached to the holding of trading stocks; (5) trusts and combinations with special reference to the protection of the consumer; (6) the establishment of new industries after the war, a committee having been especially appointed to consider this question as far as the engineering industries are concerned, a parallel committee considering the labor questions involved; (7) the volume and nature of the demand for British goods after the war; and (8) improvements in trade organization for the purpose of more economical production, distribution, and marketing, and expediting the turnover from war to peace.

The section dealing with finance, shipping and common services is, in conjunction with the Treasury, considering the question of currency and exchange after the war; and under this section an Advisory Council section is at work on the disposal of government stores after the war.

#### CONFERENCE OF TRADE ORGANIZATIONS

The section dealing with labor and industrial organizations has agreed with the British Board of Trade and the Ministry of Labor that "a concerted effort should be made to promote in as many industries as possible representative organizations to advise the Government as to the views and needs of the industries on the various industrial and commercial problems that will affect them during the reconstruction period. The Ministry of Labor is to proceed with the formation of permanent industrial councils. A conference of trade organizations is being established by the Ministry of Reconstruction, consisting of three employers, three trade unionists and representatives of the Board of Trade, the Ministry of Labor and the Ministry of Reconstruction. The Minister of Reconstruction has decided to refer to the Industrial Section of the Advisory Council the question of establishing corresponding organizations in engineering and in railways.

This section, (dealing with labor and industrial organizations) is farther along with its work than any of the other sections, apparently; for reports have been submitted on unorganized trades and works, and, probably by now, on conciliation and arbitrations. A general survey of industrial policy as a whole has been prepared, going into the law and labor in merchant shipping, war-time departures from trade-union practices, industrial courts, industrial structures, apprenticeship, the reinstatement of returning soldiers and sailors and international labor legislation. Furthermore, surveys have been undertaken of industrial methods; inquiry is

being made into juvenile employment; the question of army demobilization, it has been settled, makes the Ministry of Labor responsible for the returned soldier or sailor, and the Ministry of Reconstruction is to determine the priority of different trades. A complete list of public works which have fallen into arrears has been prepared so that surplus labor may be usefully and rapidly employed; and the Ministry of Munitions has begun work on the special problems arising out of its work.

#### RURAL DEVELOPMENT BEING STUDIED

The section dealing with rural development is examining (1) the working of the Small Holdings Act and the future of Urban War Allotments; (2) a report made by the Forestry Committee; (3) the rural housing problems; (4) the organization of County Offices for advice on agriculture; (5) tithe redemptions; (6) village industries; and (7) the report of the Land Acquisition Committee.

The section dealing with Machinery of Government, Health, Education, etc., is negotiating through a committee on the distribution of functions in regard to the formation of a Ministry of Health and is studying reports which have been made (1) on the functions of the Poor Law Authorities; and (2) on Adult Education.

The section dealing with Housing and Internal Transport, with a view to facilitating work in connection with housing, has set to work committees on (1) supply of building materials; (2) house building construction and on (3) building by-laws. Special investigations are being made by this section on (1) control of public utility societies; (2) town planning; (3) rings in the building trade; (4) the working of the Small Dwellings Acquisition Act; and a general review of the problem of inland transport is being made, the portions dealing with roads and canals having been completed. Furthermore, the Ministry is in consultation with the Board of Trade concerning the future of the railways (including light railways) of Great Britain and an inquiry has been begun into the question of storage and distribution as essential elements in transport policy.

#### SHORTAGE OF MATERIALS AND TONNAGE AFTER THE WAR

This article is intended to be but a brief outline sketch of the monumental amount of work being done by the British Ministry of Reconstruction, but it might be well here to hark back for a moment or two to some of the points being taken up by the various sections. In the section dealing with commerce and production, the report of the British War Cabinet to Parliament states that the question of the "volume and nature of the demand for British goods after the war" and the question of "improvements in Trade Organization for the purposes of more economical production, distribution and marketing and of facilitating the turnover from war to peace" are being handled in consultation with the British Board of Trade and the Department of Overseas Trade, and that "a comprehensive scheme of work has been prepared." The British Cabinet thus states the problem.

"After the war there will be a world shortage of certain materials and the shortage will be accentuated by the difficulty of finding tonnage adequate to our demands. On the other hand, there will be an almost unlimited demand for manufactured goods."

## Triplex Process of Making Electric Steel\*

Development at South Chicago of the World's Largest Electric Steel Plant Comprising Three 25-ton Heroult Furnaces—Superiority of Electric Steel—Increase in Production in Ten Years

By THEODORE W. ROBINSON

THE development of electric steel at South Chicago was based upon the fundamental conception that the electric furnace was pre-eminently adapted to the manufacture of carbon and alloy steel of the highest quality, that it would be possible to produce electric steel in sufficiently large units to permit its use in heavy products, and that the increasing demand for high-grade steel would provide a sufficiently extensive market to make its manufacture commercially possible.

Under these promises, the Illinois Steel Co., in May, 1909, installed its first electric steel furnaces at the South Chicago works. At that time there were only two other electric furnaces in this country concerned

As the fundamental object was to demonstrate the opportunities of the new process in connection with heavy products, attention was early turned to the experimental manufacture of electric steel rails. Under the limitation of equipment, it was necessary to depart from standard rail practice to the extent of accumulating cold ingots and re-heating them. The electric steel used was made from Bessemer blown metal. We advisedly felt our way in chemistry. Irregularities incident to incomplete equipment were unavoidable. In spite of pioneering difficulties, about 10,500 tons of electric steel rail were laid on 14 railroads throughout the country. The result of these rails in track indicated

TWO OF THE THREE 25-TON HEROULT ELECTRIC FURNACES

with the manufacture of electric steel—one at the Halcomb Steel Co., Syracuse, N. Y., and the other at the Firth Sterling Steel Co., McKeesport, Pa. The furnaces here and abroad were all small, running from a ton or less to five tons in capacity. Our installation consisted of a 15-ton basic-lined Heroult furnace with an electric equipment for 3-phase, 25-cycle, and 100-volt current. The manufacture of electric steel was a new art and ours was a new adaptation of a new art. As to the troubles we encountered, I may say their name was "Legion." Perseverance conquered, however, and we soon had the satisfaction of producing a metal of unquestionably superior quality.

that electric and openhearth rails of like chemical composition had practically the same resistance to wear when the former were made under the conditions that existed at the time of their manufacture. The failure from breakage was almost negligible, there were no interior defects and the tests showed that the electric steel was considerably more ductile at low temperature than either the openhearth or the Bessemer steel.

In order to further determine the facts, a series of experiments was undertaken with a view of testing the ductility of rail steel at low temperatures. A refrigerating plant was erected adjacent to our regular drop-testing machine. About 900 pieces of electric, openhearth, and Bessemer rails of various sections were tested at temperatures ranging from 70 deg. Fahr. to

\*Excerpt of a paper presented at the fourteenth general meeting of the American Iron and Steel Institute in New York, May 31, 1918. The author is first vice-president of the Illinois Steel Co.

50 deg. below zero. These tests emphasized that, in the case of all the steels, there was a marked decrease in resistance to shock as the temperature lowered. Relatively speaking, however, the electric steel was distinctly more ductile than either the Bessemer or openhearth. The following summary from two electric and two openhearth heats of similar analysis involving 242 tests is typical of the general results obtained. The figures in Tables II, III and IV are average results. The chemical composition of the heats is given in Table I.

In all these tests the height of drop was kept comparative. At normal temperatures 18 ft. was employed. At zero Fahrenheit and below, the steel, weakened by

facturing electric steel rails, we were experimenting with such other heavy products as forgings, plates, axles, and structural shapes. Not only had carbon steel been made in relatively large quantities in connection with these products, but the field of alloy steel had been comprehensively entered. Expanding demand led to the introduction in July, 1916, of a second furnace, similar to the original one in electrical equipment and capacity. This gave a combined capacity of about 4500 tons of electric steel ingots per month.

#### LARGE ELECTRIC FURNACES JUSTIFIED

By this time our experience had verified in a large measure the soundness of the views upon which our

POURING OPEN-HEARTH METAL INTO ONE OF THE 25-TON HEROULT ELECTRIC FURNACES

the cold, could not withstand so heavy a blow, and the drop was reduced to 8 ft. While it is self-evident that the number of heats involved in the above tables is entirely too small to permit the drawing of definite conclusions, the fact that the other drop tests and the result of the rails in track all pointed in the same direction warrants the belief that the resistance to dynamic force rapidly decreases with lower temperature in the case of both openhearth and electric steels and that electric steel is tougher than openhearth steel at low temperatures.

During and after the period in which we were manu-

original electric furnace installation was predicated. We had demonstrated that it was possible to produce electric steel in relatively large units without the sacrifice of quality. The physical characteristics of the steel had proved to be admirably adapted for heavy products. There was a growing demand for a superior steel for general purposes, and the call for alloy steels was rapidly increasing in connection with the automobile and other industries. Extent of market was largely a question of price, and price logically was largely a matter of cost.

In the meantime an addition to our openhearth at

South Works had become desirable and in connection therewith the matter of increasing our electric steel capacity was taken under consideration. In studying this subject, we were naturally guided by our past experience. We had made electric steel by the melting of cold stock. We had refined in the electric furnace both molten blown Bessemer metal and molten openhearth metal. We also had made steel by the initial refining of Bessemer blown metal in the openhearth, supplemented by final refining in the electric furnace. Part of this work was experimental in character. None of it was done under ideal economic conditions. The cost of producing steel in the electric furnace was vitally influenced, of course, by the amount of power used, and this and other conversion items were in turn largely influenced by the tonnage produced. Manifestly nothing could be considered that would sacrifice quality for output without destroying the very essence and reason for the electric process.

As electricity is an expensive metallurgical fuel, the melting of cold stock or the preliminary refining of metal in the electric furnace could be accomplished only at the expense of a comparatively high fuel cost. Our original practice was to make electric steel by refining

clear that for the simultaneous production of Bessemer, openhearth and electric steel, extreme elasticity of operation was fundamental if efficiency was to be attained. Close assembly of the various units was essential for rapid and economical practice. The sequence of operation had to be unobstructed. A supply of hot pig metal and preliminary refined molten steel must be provided. The plant as finally designed, both in respect to its general plant location and its general details of construction, is shown by illustrations.

Inasmuch as this paper deals specifically with electric steel, no attempt will be made to give a detailed description of the Bessemer and openhearth refining as carried out in the new plant at South Chicago. The metallurgy and manipulation present little that is novel.

There are two main buildings; one comprising the duplex plant proper, and the other, parallel thereto, containing the electric furnaces. As an adjunct to the latter, there was installed a 1500-ton forge press. In its essential features, the duplex plant consists of two mixers, one of 100 tons and one of 300 tons capacity; two 25-ton acid-lined converters, and three 250-ton tilting openhearth furnaces. The mixers are commanded by two cranes, one of 100-tons and one of 75-tons ca-

THE ELECTRIC FURNACE DEPARTMENT OF THE TRIPLEXING PLANT

Bessemer blown metal. This process necessitated two distinct operations in the electric furnace, namely, dephosphorization by the use of an oxidizing slag, and deoxidization by means of a reducing slag. Steel of the highest quality can be produced by this practice, but there is obviously greater liability to irregularity in this method than when openhearth metal is used from which the phosphorous previously has been eliminated.

It is well to remember that the electric furnace, while a highly efficient instrument, is far from fool-proof. Several years' experience with the use of Bessemer blown metal in the stationary openhearth furnaces under the local conditions that existed had helped to demonstrate the advantages of the duplex process for producing openhearth steel. It likewise had been shown that electric steel could be most advantageously produced at South Chicago by using openhearth metal.

It was essential that the proposed plant should be so designed as to provide not only Bessemer metal for openhearth refining and openhearth metal for electric refining, but Bessemer ingots and openhearth ingots as well. Many new problems were involved. It was

capacity, and the mixer metal is transferred on an elevated platform to the converters by a 25-ton transfer ladle operated by cable and winch mechanism.

When used in the openhearth furnaces, two heats of Bessemer blown metal are poured into a 65-ton ladle commanded by a narrow-gage locomotive. Elimination of slag is accomplished by nozzle pouring into a second ladle. When Bessemer ingots are to be produced, the metal from one vessel is poured into a smaller ladle and transferred to the Bessemer pouring platform. The three tilting openhearth furnaces, each of which has a hearth area of 892 sq. ft., are electrically operated, and are so constructed as to be heated either with producer gas or with tar. Air chambers having 10,472 cu. ft. of checker volume and gas chambers having 6734 cu. ft. of checker volume provide liberal regenerative capacity. Two low-type 7½-ton charging machines and three 100-ton overhead cranes assure the rapid handling of material. The pit side of the openhearth department, which is generous in its dimensions, is served by two 175-ton cranes, and is provided with a 330-ft. pouring platform capable of handling two sets of molds.

The Bessemer plant is designed for the ultimate addition of a third vessel. Its present capacity may be conservatively placed at 75,000 tons per month of blown metal, Bessemer ingots or any desired combination of the two. The three tilting openhearth furnaces when operating on blown metal are rated at 65,000 to 75,000 tons per month. The elasticity of their operation is self-evident, and it is obvious that their actual tonnage is dependent upon the character of the charge used. At the present time two of these furnaces are running on openhearth material, with Bessemer blown metal as a base. The other furnace is operating on a nickel steel scrap charge with molten pig iron additions for further refining in the electric furnace.

In transferring openhearth metal to the electric furnaces, it is the aim to have the metal slightly lower in carbon and manganese than the specifications under

in the small furnace to consider the losses due to resistance in the electrical current. When we consider the relatively little power required by the original furnaces, it is evident that in the case of our larger furnaces which are equipped with transformers of 3750 kva. capacity, the question of power losses is an important one. In respect to the electric furnace load from the central station standpoint, it is interesting to note that with four furnaces operating on the triplex process, 24-hr. load factors of 75 or 80 per cent are not unusual. This compares favorably with other forms of industrial load.

In our practice, the furnaces ordinarily are operated with only a reducing slag, and care is taken at all times to see that such conditions obtain as will most thoroughly and quickly effect complete deoxidation. After the steel is thoroughly dead-melted and the reactions

THE TRIPLEXING PLANT OF THE ILLINOIS STEEL CO., SOUTH CHICAGO

which the electric steel is to be made. There is, of course, oftentimes a wide range in the specifications under which the electric furnaces are operating, involving high and low carbon and various alloy steels.

### THREE 25-TON HEROULT FURNACES

The new electric plant contains three 25-ton Heroult furnaces, each with an adjacent transformer building. The general design and dimensions are shown by one of the illustrations. The capacity of the plant naturally is somewhat dependent upon the character of the steel made, but may be placed approximately at 12,000 tons per month. This with the output of the two old furnaces gives a total electric steel capacity of 16,000 to 17,000 tons per month, and makes the South Chicago works the world's largest electric steel producing plant.

The advancement in the design and operation of electric furnaces has not necessitated any radical change in the original electrical scheme as a whole. Such improvements as have been made have been rather in the nature of refinement than essential change. In the case of the large electric furnaces, it is more necessary than

are complete as determined by the careful testing of the slag and metal, the current is reduced until a proper pouring temperature is obtained.

### PYROMETRIC CONTROL OF TEMPERATURES

The pouring of steel from the electric furnace is subject at all times to the careful control of pyrometric observation. For the production of a satisfactory steel, a proper casting temperature is an important element in all processes, but with the electric furnace special care is needed, partially because of the high heats obtainable with the electric arc. Electric steel on account of its freedom from gases is specifically a dense steel, and in metal of this character the pipe tends to be exaggerated. It is our custom to teem all electric steel in inverted molds with refractory hot tops. As a result, little difficulty is encountered either with the piping as usually found in the ordinary ingot.

As to alloy steels, it is very necessary to guard against any condition that will unduly tend to unequal ingot strains and special precautions are taken to avoid undue surface tension in the molds. We are now cast-

ing ingots weighing from 3,400 lb. to 38,000 lb., the uniform solidification of which is made the subject of the greatest care. Top pouring, box pouring and bottom pouring are resorted to, as the individual character of the steel best appears to warrant, and the entraining and inclusion of slag or other foreign matter is carefully guarded against.

To one familiar merely with the casting methods in vogue with ordinary openhearth or Bessemer steel, the pit practice incident to the proper manufacture of electric steel is something of a revelation. In the subsequent work to which the ingot is subjected, whether in the forge or in the rolling mill, special precautions are taken in the heating, in the reduction of the metal and in the cooling of the product. Ordinary mill practice will by no means suffice if proper results are to be obtained, especially when alloy steels are concerned. Steel which may be innately of the highest quality when tapped in the ladle may readily retrograde or become unfit unless there is exercised extreme care in its later manipulation. Quality is peculiarly the *sine qua non* of electric steel and the price of success is eternal vigilance. There is of course nothing occult nor mysterious in the electric method, although there is more or less misconception concerning the production of electric steel. The electric furnace when used for the manufacture of steel may be likened to a large crucible heated from within instead of from without by the electric arc. It is capable of performing not only the functions of the openhearth but very largely those of the crucible as well. Its superiority lies in the rare purity of the heat derived from the electric current and in the peculiar slag control that can be commanded in a neutral atmosphere.

#### SUPERIORITY OF ELECTRIC STEEL

Both the Bessemer and the openhearth processes are distinct in their physical and metallurgical character. The electric process may likewise be considered as distinct when concerned with the manufacture of steel directly from cold metal. When, however, it is used to finish metal which previously has been made in the Bessemer or openhearth, it may be considered as supplementary to standard methods rather than as

an independent process. Other than as manufactured in the smaller and perhaps more ephemeral installations, electric steel is to-day, and probably will be in the future, largely produced by a duplex or triplex process whereby, strictly speaking, steel is electrically refined rather than electrically made.

#### FUTURE METALLURGY OF STEEL

And now a word as to the future: I am not unmindful that "a prophet is not without honor save in his own country." Moreover, human limitation and the kaleidoscopic changes of the past make one hesitate to forecast the metallurgy of steel. While ours is the age of steel, it has been given to men here present to see the passing of the age of iron. The crucible is hoary in its antiquity. The converter a short generation ago was but a conception in the mind of a man whom many of us know personally and the openhearth as an essential factor is even more striking in its adolescence. It behooves one, therefore, to be conservative in his prognostication. Forty years ago this country produced but little over a half million tons of steel, 90 per cent of which was made by the Bessemer process. Last year we made 43,000,000 tons of steel, and to the openhearth 75 per cent is to be accredited. While our production of Bessemer steel has remained nearly stationary since 1906, when it reached its zenith

POURING PIG IRON INTO THE 1300-TON MIXER AT THE ILLINOIS STEEL CO.'S TRIPLEXING PLANT

with an output of 12,250,000 tons, the openhearth has rapidly forged ahead, and last year it accomplished over 32,000,000 tons.

The marvelous development in Bessemer steel was due both to its superiority for general purposes as compared with wrought iron and to its relative cheapness of production. The more recent expansion of openhearth is attributable, not alone to changing ore conditions and to the lower cost incident to modern construction, but to the increasing demand for a higher quality of steel. The passing of the Bessemer plate and the Bessemer beam and channel was only a prelude to the replacement of the Bessemer rail by its openhearth rival. It is true that steel made by the Bessemer process is admirably adapted to certain products and for many years to come will play an important part in the metallurgical economies of our nation, but the glory

of the converter has definitely paled before the more enduring reliability of the openhearth. In the earlier stages of our steel manufacture, tonnage, as an essential element of cost, was a dominant consideration. Neither the mill nor the consumer attempted more than a general differentiation as to the character of the product. It was largely a matter of quantity and price. Now quality stands first and, while tonnage has gone on apace, volume has become more and more subordinate to character of production.

What does this increasing demand for higher quality portend for electric steel? How much is history to repeat itself in connection with the new process? It is clear that the lower the cost of production, the greater will be the field presented, and much will depend upon the ironmaster's ability to reduce the cost of electric refining to a minimum. When we realize the economies that have been commanded with the openhearth furnace during the last 20 years, it perhaps is not unreasonable to anticipate that much may be accomplished along similar lines with the electric furnace.

#### FUTURE INCREASE IN PRODUCTION OF ELECTRIC STEEL

If one is intelligently to read the future, he must take into consideration both statistics and psychology. The annual statistical report of the American Iron and Steel Institute first separately classified electric steel in 1909, with a production of 13,762 tons. Last year this country produced 234,000 tons, which is more steel than was made annually in all our openhearth furnaces 30 years ago. The output of electric steel this year undoubtedly will be much greater. We are now producing at the South Chicago plant at the rate of 140,000 tons per year, and we shall shortly be producing at the rate of 200,000 tons per year. Our country is growing rapidly, and the per capita consumption of steel is growing even more rapidly. In 1900, our population was approximately 76,000,000, and each of our inhabitants represented an annual consumption of 280 lb. of steel. In 1916, our population had reached 103,000,000, and our annual consumption of steel had increased nearly three-fold, to 820 lb. per capita. These figures do not include our exports of nearly 5,250,000 tons made that year. So much for statistics.

As for psychology, we should not forget that the luxury of today is the necessity of tomorrow, and that emulation is a powerful creative force. Bessemer steel was eminently satisfactory until the superior quality of openhearth metal relegated it to a subordinate class. And now comes electric steel with a still higher standard. Safety cannot be measured by price and public opinion will more and more insistently call for the highest excellence in the automobile, the airplane and other forms of fabricated material.

Forty years ago Sir Williams Siemens dreamed of making electricity the handmaiden of the metallurgical art, and through his efforts his dream was realized in the birth of electrometallurgy. Twenty years later, Heroult visualized the dominance of electrometallurgy in the realm of steel. Whatever the future may have in store, let us remember that progress waits upon vision, and vision, even though it resolves for the moment into a mirage of shattered hope, often is ultimately translated into accomplishment.

## Research Preparedness in the Zinc Industry

BY PARKER C. CHOATE

**A**CTION and reaction are equal but opposite. The nearly stimulation of spelter production by the war has caused over-production with a consequent drop in prices to the point where no material profit accrues to the distiller. This condition of affairs will soon be followed by sharp competition and the survival of the fittest, in other words, of those who possess the cheapest mineral values coupled with the cheapest method of extracting the maximum metal contents. Since zinc is perhaps the most prevalent of all metals except iron and aluminium in the minerals contained in ore bodies, the coming struggle involves the technical efficiency of the metallurgical process or the economical treatment of the complex ores of zinc rather than the procurement of the selected grades of concentrates.

In the following matter I will describe the general metallurgical present and future, as it appears to me, using broad lines of comparison, showing the commercial relations and the forces that will bring the radical changes for those who live by the zinc industry. Briefly, we must create the art of volatile concentration. We must briquet all retort charges, and proper briquetting involves pre-reduction and coking. We must adopt the vertical retort. We must make the gas as a costless by-product fuel. We must extract the lead, silver, and other valuable metals from the raw sulphide by leach electrolysis. This done, with the associated acts, we are led to a much cheaper operating cost, a better extraction, an easier labor problem, and an indifference to the relative metallurgical complexity of the zinc concentrate handled.

I do not aim to give details of operation, which however are largely at hand; on the other hand I will not picture any act or result that is not obvious through tests, by analogy, or by known metallurgical science. I can merely point the way in such a brief outline, but can submit details of practically all the statements, admitting that much is novel in either degree or principle.

It will be a great benefit if this radical picture brings out a full discussion. Such is needed for the well-being of the art, since no branch of metallurgy is in more need of advance.

#### PROCESSES NOW IN USE

At present we are using retort distillation just as it was forty years ago. Acid manufacture was introduced as a necessity, while the volatile treatment of residues is unsound since they should have no value to extract.

The volatile practice is antiquated. Recently there have been several attempts to distill zinc in an electric furnace, none of which survive because of expense and inefficiency. However, there will probably appear a radically different process of electric smelting which will survive. It will be operated at the mines, without roasting the ore, and will save in one act over 90 per cent of the zinc, lead and silver as metals. The saving on freight charges and in expensive reduction plants is obvious.

Under the stimulation of war prices for chemically pure zinc a successful process of refining spelter by electrolysis has been established, analogous to the well known electrolytic refining of copper. This industry is

very creditable and perhaps profitable for a time, but its only future would appear to be in connection with the electric smelting described, which may produce a spelter carrying lead and silver as by-products.

We have also several examples of leach electrolysis using so-called insoluble anodes, the solutions being prepared by leaching roasted ore or a zinc-lead-silver fume. Leach electrolysis is with us to stay because up to a certain quantity the almost pure zinc will command the market. Furthermore, it is a very attractive process in the hands of mine owners who also have cheap water power and who now look upon the zinc content of the ore as a liability rather than as an asset.

In my opinion, the leaching of fume is the cheaper of the two methods when volatile concentration is efficiently practiced. In passing it might be mentioned that a true insoluble anode does not exist, and perhaps never will, due to the great destructive action of electric dissolution.

#### VOLATILE CONCENTRATION

Experiment shows that the art of volatile concentration gives a heat balance comparable to that of the usual boiler practice, the heat being conserved by a special design of flash boiler and hot-blast stove. The boiler and stove are to be made of prepared tubes which resist oxidation up to 800 or 1000 deg. C., and have entirely vertical surfaces automatically cleaned of dust. Since the blast is to be heated to a temperature above the ignition point of the fuel bed, it is obvious that no wet-tube water-circulating boiler can be used, because the boiling point of water is about one-half the ignition point of coal.

The fume is to be precipitated by electrostatic action from cooled gases. A mechanical bag-filter may finish cleaning the gases of the last fraction, as this work is difficult under electrostatic action.

Special stokers built on lines used in coal burning are to be used to charge the mix into the retorts. The admixed fuel may be reduced to 15 or 20 per cent of that now used, and if credited with the heat conserved in steam as power, may be under 10 per cent.

Zinc carbonates, silicates, residues, and low-grade raw sulphides may thus be heavily concentrated with high extraction of silver, lead and zinc at nominal labor and fuel costs. The conditions described above constitute a new art as compared to any existing practice.

#### LEAD AND SILVER EXTRACTION

I would propose to reverse the usual practice and extract over 90 per cent of the lead and silver values together with a large proportion of iron, if so desired, from the raw concentrates before decomposing the zinc blende, by a process of electrolyzed leaching. The solvent will be regenerated, and the power costs confined to the current necessary for deposition of the small weight of lead, silver, copper, etc., that is electrolyzed. This step may pass to the mine operator as an adjunct to flotation, rendering the most complex ores metallurgically as simple to the zinc smelter as the best Missouri blende. This process will perhaps be cheaper and doubtless much more efficient than the smelting of residues.

#### SULPHURIC ACID

I see little value to the zinc distiller in making acid. When he realizes the trouble he avoids and the benefits he gains from distillation of raw sulphides the practice

of acid making will cease. He may more profitably make the metalloid sulphur from the calcium sulphide residue, as it has ready sale and moderate freight charges to market. However, manufacture of acid may precede or follow distillation. It may be made from the sulphur extracted from the calcium sulphide residue or it may be omitted altogether with no sulphur smoke nuisance.

#### BRIQUETTING

The briquetting of the entire retort-mix is a coming necessity, whatever the distilling practice. Good briquetting practice uses 6 per cent pitch as a binder, a compression of from 2000 to 5000 pounds per cubic inch, followed by coking at 400 deg. C. (or up to 800 deg. C. if cadmium and lighter impurities are to be removed). Caustic lime in the briquet requires special knowledge or hydration will take place during handling. Properly made briquets cost about \$1.00 per ton, including pitch and baking, are almost as hard as natural ore, conduct heat twice as well as the usual mix, and, if lime is used, reduce the zinc in residues to one per cent irrespective of the complexity of the ore, avoiding slagging action on the retort at the same time. Because of ideal contact reactions due to fine grinding and mixing, briquets use only about 25 per cent of the carbon in the usual mix. Their use also reduces the iron that usually passes to the spelter mechanically. Briquets should not be over  $\frac{1}{2}$  inch in cross section.

#### FUEL GAS AND CARBON MIX

The best carbon for retort mix is the pulverous residue from low-temperature retorting of non-coking or lignite coals. This carbon is economically produced from local coal slack. Since it supplies valuable by-products of distillation such as tar and tar oils for flotation as well as a large excess of its own gas of distillation, that carbon used in the retort mix will be produced at no cost. As will be shown later, the entire fuel gas required for distillation of the zinc may also be a costless by-product of the manufacture of domestic briquets.

If we assume that it usually requires 125,000 cubic feet of natural gas to distill one ton of spelter, it may be assumed that recuperation of waste heat will reduce this to 75,000 cubic feet. If, now, we use the lime-briquet charge in the retort, it has been shown that one-half this fuel is saved by reducing the time and temperature of distillation. It is then practicable to use no more than 40,000 cubic feet of natural gas to produce one ton of spelter.

One ton of Illinois coal will produce 7500 cubic feet of excess gas, net, of about three-fourths the calorific power of natural gas, together with about 1500 pounds of carbon residue and a quantity of valuable by-products more than capable of paying for the cost of retorting. The briquetted residue will sell as domestic fuel for more than the cost of the coal and freight bills. The residue produced from low temperature distillation contains some undistilled hydrocarbons, makes the ideal retort mix, and briquets properly into an ideal domestic fuel in a section of country devoid of such.

If in a briquetted retort-mix with roasted or raw ore we use one to two pounds of carbon per pound of spelter produced, we may calculate: For one ton of spelter we must manufacture 50,000 cubic feet of gas of 600 to 700 B.t.u., from about 6 or 7 tons of slack coal, producing

at the same time 3.75 to 4.5 tons of carbon residue with the usual tarry by-products. We use in our mix up to two tons of carbon per ton of spelter produced, and consequently sell 2.5 to 3 tons of briquets and other by-products at a material profit.

#### RETORT FURNACES AND DISTILLATION PRACTICE

The labor problem in present distillation practice is serious and expensive. It is obvious that the use of vertical retorts will cut labor bills heavily and reduce the amount of specialized labor necessary. It will further reduce retort costs, since more enduring retorts can be made up to 20 inches in diameter. A dead-core retort can be provided giving a larger ratio of volume to circumference with no greater depth of heat penetration than in the present practice. Vertical retorting can also be made continuous, as has already been done.

I believe that the briquet made with raw ore and burned lime is the charge of the future. The virtues of this mix will gradually be appreciated by operators after actual practice. Should the distiller desire to continue roasting, he may do so and hold his residues down to one per cent of zinc, irrespective of the degree of roast, by using under ten per cent of lime. However, the raw-ore briquet is the better heat conductor, acts better in the retort, and requires the lower temperature for the reaction. If there is any real value in the sulphur content of the ore it would seem best to reclaim it from the calcium sulphide residue.

The firing of retorts should be by small gas jets. Pulverized coal will be found a most efficient auxiliary and can be introduced through the same jet system. I can see no future for the large single-flame burner. Pulverized coal firing is well established, offers large savings and economies over producer practice, and produces heats much better under control. It is practiced best with the dead coals or carbon residues and involves the same principles of draft and pressure as gas firing, while the fine ash produced by powdered coal is understood and handled better than the slags formed in producer-gas firing. In special locations the combined use of retort gas and pulverized carbon may be the most economical, but not where a civic population can consume a domestic briquet in quantity.

Recuperation of waste heat can now be performed in specially prepared iron pipes which easily withstand oxidation up to 800 to 1000 deg. C., and even more for a limited time. This item materially affects plans for conservation of heat.

#### QUALITY OF SPELTER

If we remove lead by leaching concentrates, none will enter the spelter. The same may be said of the iron; but in this case, the lime briquet permits only small quantities of iron to pass over into the spelter mechanically, the amount not increasing even in the third draw of metal, even with concentrates up to 10 per cent of iron.

Cadmium, together with other lighter impurities, may be largely removed in coking the briquet, simply by raising the temperature to about 800 deg. Centigrade.

#### ECONOMIC FORCES

Past practice will be abandoned for that which will produce a cheaper metal, owing to the over-stimulation

in production and the existence of other methods than zinc distillation, but more especially to the demands of labor and the increased cost of coal. Thus the forces of necessity will soon make technical efficiency the dominating factor among zinc distillers. It will no doubt be difficult to abandon large investments in furnace equipment, and many directorates will be incapable of seeing the necessity of so doing, but those who do not will be forced to give way to those who do. The economic forces must rule. Conservation is the root of economy, and the dominant factors in this instance are fuel and labor.

#### CONCLUSIONS AND COMMENTS

In reviewing the subject, perhaps I see the more merit in the fume-leach-electrolysis idea because I invented and practiced it twenty-five years ago; but today I see the chances for improvements in volatile concentration and the possibilities in the use of a composition anode.

I am satisfied that the small electric smelter will find a place in the hands of the mine operator, there being by-products in metals to save and freights to reduce. The removal of lead and silver prior to distillation will materially enhance the value of the complex zinc ores to the mine operators.

The greater changes are necessary in distillation practice, and their economies are obvious. They must offset the heavy freight bills by materially raising the extraction and by the conservation of heat and labor. Research shows that briqueting will solve the domestic fuel question for the Middle West, since the distillers have a use for the gas, while the domestic consumer will be provided with a fuel fully equal to anthracite at a lower cost.

There would appear to be no larger public service of lasting kind than the double act of giving the West an ideal economical fuel made from their local non-coking coals and lignites, and placing the zinc distillers on a firm basis to meet the impending competition with leach electrolysis and electric retorting processes.

Today the Western public largely loses the volatiles of their local coals in their commodity use, with the simultaneous production of a smoke nuisance. If the local coals are carbonized and briqueted as is already practiced in a small way, there is difficulty in selling the excess gas produced. The zinc distiller must use gas, but if he uses producer gas, he does so only at a great sacrifice, since it has a low calorific intensity and no by-products are saved. The economies accruing with low-temperature carbonization aggregate large figures.

Definite experimentation will be along radical departures, but for that matter, so was the flotation process. A working unit of industrial size alone can show the economies. "Seeing is believing" to the business mind, no matter how clearly the engineer makes his figures and deductions.

Following the lines of conservation, why would it not be good business for several large interests to join in this radical research? In this manner the inevitable duplication and the patent war could be avoided. The zinc distillers centered in a thickly settled community in the Middle West can do the community a large service at a profit to themselves under the research outlined above.

Essex, Mass.

## The Rubber Embargo

### Economic Effects of Reduced Rubber Supply— Reclaiming Old Stock—Guayule as a Local Source of Natural Substitute

BY ANDREW H. KING

SOMETHING over a year ago the writer published a series of three papers dealing with the crude rubber situation, and pointed out as a matter of national preparedness that our country should be, at least in some measure, independent of foreign sources of supply. The incentive which led to these papers was the spectacle of a modern nation suddenly deprived of its supply of crude rubber. We know absolutely that the blockade has touched a very vital spot in the German armor. If kept tight enough and the war lasts sufficiently long, the absence of rubber may ultimately become one of the straws which will break the camel's back. One very pertinent instance may be cited. The Allies now have one of the most elaborate systems of gas defense that can be devised. Every man and every animal liable to gas attack has his gas mask. These masks are quite effective and give absolute protection against all of the gases as yet used by the Huns. They consist primarily of rubberized fabric. The Germans have no rubber so make their masks out of leather. As a consequence they are stiff, hard to put on, and do not fit well. Allied gas attacks are in many instances successful because of the length of time required to adjust the enemy mask.

#### TRANSFER OF SHIPPING CURTAILS CRUDE SUPPLIES

Little did the writer, or any one else for that matter, imagine that there was any immediate danger of even a curtailment of our crude rubber supply. We thought it something worth thinking about for the future, but no one dreamed that such a situation would develop so quickly. The possibility of a hostile fleet blockading our shores was then, and is still, remote; but the contingency which very few if any of us realized was the great efforts which we were to make on entering the war. Those who are in a position to know say that the greatest trouble has been to make the American people realize what an enormous responsibility rests upon them. The war on barbarism is not to be a side issue nor any sort of a picnic. We are in this thing and for the sake of posterity we must not lose. Our effort must be that of a whole united people. The ultimate decision rests largely upon the American public. We hold the balance of power. If we get into the harness as efficiently and as completely as the French and British, there can be no question of the outcome. There is every evidence that we will equal if not exceed our allied friends in this business of war. The progress which has been made in the first year has been really remarkable. There has been very little grandstand playing and hip-hurrahing, but the wheels have been made and fitted together. Now they are beginning to turn. While all that has been done is due primarily to the spirit of the people, yet no small credit must be given those who by helpful criticism sought to correct evils and mistakes of management.

The present situation on the Western front is an

extremely critical one. Germany has already tried out the mettle of American soldiers and has found it better than her most pessimistic observers ever had the nerve to admit. She is well aware of the great organization now getting into low gear and she knows perfectly well that such a steam roller will finish her dreams of world conquest when it gets properly working. Her only hope for victory is to defeat the French and British before our strength becomes a deciding factor. This is the reason for the spring offensive. If Hindenburg can break the allied armies within the next six months regardless of what it costs him in lives or in money, Germany will win. Such a calamity is not impossible. In fact, the chances are almost fifty-fifty now. Our brave allies must bear for just a little longer the combined might of the German war machine. So it becomes imperative that American soldiers be sent to France just as fast as sufficient ships can be furnished for their transportation and to keep them supplied. The slogan "Ships will win the war" is absolutely true. The submarine warfare of the enemy, while not successful, has made a great dent in the world's shipping. Because of this emergency ships are being withdrawn from all possible peaceful pursuits, and we are brought face to face with a new paradox, a blockade of ourselves by ourselves in the interest of national safety and world progress. There are not yet sufficient ships to handle normal commerce and to transport the troops with their supplies. When our shipbuilding program gets under way this condition ought to be considerably bettered, but for the time being peaceful trade must suffer.

The situation is, of course, not nearly as serious as an enemy blockade but the curtailment of raw material will be keenly felt not only in the rubber industry but others as well. In the matter of shipping, rubber is rather a serious offender since such a large space is required to carry comparatively a small weight, and the distances to be traversed are so enormous. The specific gravity of rubber is about .93. Its weight per cubic foot is 58.1 lb. So to transport a ton (2000 lb.) of rubber the very least space required would be 34.4 cu.ft. As a matter of fact the actual space necessary is about 20% greater, making it about 41 cu.ft. America imported last year about 157,000 tons of rubber. The cargo space occupied was approximately 6,500,000 cu.ft.

#### SOURCES OF OUR RUBBER

Much of our rubber comes from the far East. In 1916 only 23% of the 116,477 tons consumed was imported from South or Central America. Most of the 77% remaining (very little comes from Africa now) was plantation rubber from the Far East. The distances are tremendous. Singapore, which is located on the tip of the Malay Peninsula, Federated Malay States, is probably the most important marketing place for crude rubber in the world. The old route now closed because of submarine activity in the Mediterranean was by way of the Red Sea, Suez Canal, Mediterranean, London, and thence to New York. The distance is 12,900 miles. This made London the neck through which nearly all the crude rubber in the East had to pass. The new route is by way of Honk Kong, Yokohama, Honolulu, to San Francisco or Seattle, and thence by

rail to Akron or New York. Singapore is 8460 miles from San Francisco, which is approximately 3000 miles by rail from New York, making a total of 11,460 miles. An all water journey from Singapore to New York by way of the Panama Canal is 11,760 miles long. By way of comparison, the port of Para in Brazil is 2600 miles from New York. During the past two years a constantly increasing tonnage has been shipped direct from the far East to our Pacific ports. It requires no stretch of the imagination to see that a great deal of shipping is required to supply us with crude rubber. Any curtailment in this supply will set free a respectable number of first-class freighters which are badly needed for the troops.

This is exactly what the Federal War Trade Board wishes to do. There is no desire to work undue hardship to the industry and as a consequence the first plan proposed, which will be in operation before this is published, is to be effective for only three months, after which the working will be reviewed and such modifications as are necessary will be made. The plan is as follows:

During 1918 there are to be only 100,000 tons of crude rubber imported, which figure is 57,000 tons less than the official estimate for 1917. The 100,000 tons includes a quantity of 35,000 tons which the government reserves for strictly war purposes. This rubber will be used in gas masks, balloons, truck tires, auto tires, proofing, etc., and the figure is none too high. This leaves only 65,000 tons to take care of normal peace time activity. The official figures for net consumption for the past five years are as follows:

|         |                                            |
|---------|--------------------------------------------|
| 1913... | 49,850 tons                                |
| 1914... | 61,251 tons                                |
| 1915... | 96,794 tons                                |
| 1916... | 116,477 tons                               |
| 1917... | 157,000 tons (About 170,000 tons imported) |

During 1918 there will doubtless be quite a decrease in demand for rubber goods for civilian purposes, but even on the basis of 1916, which will probably be about right, our rubber factories will face a shortage of 51,500 tons. In other words, the supply of crude rubber for ordinary purposes is to be cut in half.

Rubber on hand or in transit is not affected. The large companies have on hand from four to six months' supply. A department with which manufacturers may deal directly in importing rubber has been established by the Trade Board in Washington for the period of the war. Crude rubber can only be imported by obtaining licenses from this department and guaranteeing that the amount purchased is within the restricted quantity fixed by the government. Prices have already been fixed, varying from 62 to 68 cents per pound, depending on the grade of rubber imported. Prices on manufactured articles have not yet been fixed but probably will be if there is any tendency towards inflation.

In certain quarters there is a disposition to meet the new turn of affairs with an optimistic feeling that three months will see the end of the embargo, that after this time ships can again be spared and that the government will see the fallacy of throwing thousands of men and women out of work, etc. Such an attitude shows a woeful lack of foresight. Within three months the large companies will doubtless be

swung over to meet the new conditions. No one gauged correctly the huge effort that America would make in the war. The first plans were for an army of 2,000,000 men. Now it is proposed to put an army of 10,000,000 men in France. The demand for shipping will increase rather than decrease and the present curtailment will likely prove to be only the first pinch. Within three months we may be asked to take a further 50% reduction, and it is not impossible that within a year we may be importing only enough rubber for war needs. This does not by any means sound the death knell of the American rubber industry. The men directing it are big enough and resourceful enough to weather through. The fate of the small companies, poorly financed and without extensive organizations, is more doubtful. There may even be several failures.

#### OUR INDUSTRIES ARE OUR EFFECTIVE RESOURCES

There is another angle to the situation which may well be given a brief mention here. On all sides we hear slogans—that food, ships, etc. will win the war. All these are merely incidentals. There are but two fundamental necessities—Spirit and Money. The first

THREE YEAR, TWO YEAR, ONE YEAR  
GROWTH OF GUAYULE OR GRAND CUT-OVER

we have in large measure and need not be further discussed. The second we have also, but its application is a little different. The huge and heretofore unheard of sums of money spent every day by the opposing armies are understood by all as well as our powers of imagination permit. Such a stream of gold is required to feed the war machines that it would be well to look at the source. All money is the fruit of business and the product of industry. We must keep the source of money in good condition.

There are two ways of paying for the war: One is to tighten the belt a few notches and take it out of savings. This excellent idea is embodied in thrift stamps and in the bank plan for Liberty bonds. The other is to make the money by extensive trading with

neutral countries, selling them more than they sell us. This last is all very well provided there are any neutrals and they have the money to purchase with. Our greatest markets are now South America and perhaps China, in both of which extensive selling campaigns should be carried on and for which efforts to give passable steamboat connections should be made. Manufacturing for home consumption will be limited more and more to those things which are essential and non-essentials will go by the board. But for export to neutrals we should make everything there is any demand for, whether it is essential or non-essential.

About 70% of the crude rubber imported goes into automobile tires. The tire is part and parcel to the automobile whose only purpose is transportation. The machine can no longer be looked upon solely as a pleasure car, i.e., a non-essential. By far the larger portion of American automobiles are real necessities. They are the best antidote for the tendency of modern men and women to crowd into large cities and bring about undue congestion. They are now as firmly woven into our national life as the horse was 30 years ago. Auto tires are essentials and should be considered as such. Consequently their manufacture for certain purposes should not be reduced to the point where it will work a hardship to the car owner. The service of truck tires needs no comment. They are just as important to the army behind the line as to the soldiers in the field.

The position of the rubber manufacturer is unique. For patriotic reasons he must import as small a quantity of crude rubber as possible and for other equally patriotic reasons he must keep his countrymen supplied with all rubber products which are essential. But what may he use in place of crude rubber? Synthetic rubber is not a commercial possibility. With the advances which have been made in rubber tree cultivation such an industry is now impractical. There are only two solutions, both of which are required. They are shoddy and guayule.

#### SHODDY

By shoddy we mean reclaimed rubber. The methods of reclaiming were discussed by the writer in a previous paper (this *Jour.*, Mar. 15, 1916, p. 310). The most satisfactory and most generally applied process is that of A. H. Marks, U. S. 635,141 Oct 17, 1899, which has now expired. This procedure consists essentially of digesting finely ground waste in a 3% sodium hydroxide solution at 125 lb. of steam (344° F.), with stirring for 24 hrs. more or less as required.

Many factories have their own reclaiming plants and there are numerous firms which make it their sole business. The machinery for extensive production of shoddy is at hand and will doubtless be used to the limit of capacity. A better organization among the scrap dealers would be desirable as would be a better co-operation between the consumers of rubber goods and the scrap gatherers. The public should be instructed as to the importance of the smallest piece of scrap rubber, and all worn out articles should find their way to the reclaiming plants.

But the reclaiming plants cannot produce a shoddy the equal of crude rubber. Germany has had to de-

pend upon them alone and we know how she has failed. The quality of her rubber goods has declined to the vanishing point. The function of reclaimed rubber is merely to stretch the crude rubber supply and not to replace it entirely.

#### GUAYULE

The real load will ultimately fall on guayule, which can be imported from Mexico by rail. During the past six years the harvesting of guayule has been greatly retarded by the unsettled condition of Mexico's internal affairs. Happily things now seem to be improving. Some one has evidently spoken a soft word to Carranza and the German agents appear to have cast Villa adrift. Mexican guayule is now being placed on the market by at least two large corporations.

In the years before the revolution Mexico annually produced about 10,000 tons of guayule. The decline began in 1911, by 1912 it was only 3500 tons, in 1914 but 728 tons. 1915 saw an increase, the production

GUAYULE SHRUB.

amounting to 2555 tons. For the twelve months ending June, 1916, was 1408 tons.

In the above I have stated that the action of the War Trade Board has created a shortage of over 50,000 tons of rubber. The all important question now is—can this deficit be made up with guayule? Endlich estimated that up to 1909, 225,000 tons of shrub had been harvested, which was about half the supply originally available. By best methods of treatment the shrub yields 9.5% rubber, based on the dried weight. If Endlich's estimate were true there must have been only 22,500 tons of rubber available in 1909. But Mexico has exported since then something like 30,000 tons of guayule, so it must be concluded that he was entirely too conservative. To estimate with any degree of accuracy the shrub content of such a large area is almost impossible owing to the irregular nature of the separate groups.

Since 1912 there has been but very little harvesting in the great Chihuahuan district. Since 1910 more care had been taken in gathering the plants. They were not ripped out root and all as in the old days, but were neatly cut off at the ground. This left the root system intact, so that it would send up shoots which could branch out and produce a bush at least 16 inches high in five years. Fifteen years is required for guayule to grow from seed to maturity in the desert. There ought to be great quantities of new

plants available, to say nothing of those which must have grown from the roots of plants previously cut. It is now six years since the Mexican trouble started. A very safe estimate of the shrub now available may be placed at 500,000 tons, which when harvested should yield about 50,000 tons of rubber.

This takes no account of the rubber produced by our own Southwest. In 1911 there were 6,000,000 acres of guayule growing wild in Texas which is in the same belt as the great Chihuahuan desert. There is also the factor of cultivated guayule which will soon be of considerable importance. The International Rubber Company now has rather a large plantation near Pacheco, Arizona. This is being gradually increased. It is said that the present extent is near 10,000 acres. This company is said to be backed by the Standard Oil Company, and has a capitalization of \$29,000,000. It still controls a number of large plantations in Mexico.

#### PRODUCTION INCREASED BY INTENSIVE IRRIGATION METHODS

DeKalb claims that in California guayule under irrigation has been known to produce as much as 28% of its net dry weight in rubber. He also states that by four year intensive irrigation methods 25 tons of the dry plant may be grown per acre. The best scheme is to irrigate with plenty of water until the plants become sufficiently large and sturdy. The water is then shut off for six or eight months, during which the plant produces rubber in the tissues. At the end of this time irrigation is resumed and is continued till a new growth takes place, after which the water is once more shut off. This procedure is repeated until four years have expired, when the plant is ready for harvest.

The proposition of guayule plantations is one which has been neglected long enough. It is time for American business to get behind it and to push it along. Such an industry would be a financial success, paying it is conservatively estimated 8% without irrigation, or \$180 per acre per year on irrigated land.

#### OBSTACLES IN WAY OF USE

To swing over completely to guayule from plantation rubber would now be quite a hard task since it has been out of the field so long. There are now not many of the old compounders left who handled it in the days when it made up about half the crude rubber used in the country. Employed alone without treatment it is not satisfactory for high grade stocks. However, it can be blended with plantation rubber (Hevea) with reasonably good results. If one is to get the value out of guayule it must be deresinated. It contains approximately 25% resin, which behaves somewhat like so much oil and has a dissolving and softening action on the rubber. This comes into play during vulcanization and later when the article is in service. The extracted resin may be disposed of by milling it with dry shoddies, on which it has rather a beneficial effect.

There were in this country at one time about fifty deresinating plants, nearly all of which have now been dismantled or turned to some other purpose. Before the country can again make use of guayule to the best advantage new plants must be built and perhaps new procedure adopted.

### Plans for Preferential Fuel Distribution

Plans for the distribution of coal within the various states have been formulated and put into operation by the United States Fuel Administration. This plan is designed to define the responsibility and authority vested in the State Fuel Administrators for the distribution of the coal allotted to their respective states, subject to general instructions issued from time to time from Washington.

The War Industries Board will decide what consumers shall have preference in securing coal; but the United States Fuel Administration has been asked to assist in the compilation of complete preference lists of obtaining reports and recommendations on individual firms from the State and Local Fuel Administrators.

The crux of the new distribution plan lies in the compilation of these preference lists. All consumers of coal, except domestic consumers, will be recorded under the following classifications:

- (a) Railroads,
- (b) Army and Navy, together with other Departments of the Federal Government.
- (c) State and County Departments and Institutions,
- (d) Public utilities,
- (e) Retail dealers,
- (f) Manufacturing plants on War Industries Board's preference list,
- (g) Manufacturing plants not on War Industries Board's preference list.

The first six classes will be given preference in coal shipments in co-operation with the plants of the War Industries Board.

The distribution of coal to consumers in the first two classes will be handled from Washington. Washington will also supervise shipments to a few vitally important plants.

The list of consumers entitled to preference as established by the War Industries Board will be obtained through a questionnaire sent to every manufacturing plant in the country using more than 500 tons of coal annually. This list, when compiled, will be furnished to each Fuel Administration District Representative in the producing fields which supply the various states; and with these lists to guide them, together with weekly reports which will be required from each manufacturing plant, the State and Local Fuel Administrators and District Representatives will give their particular attention to building up proper stocks of coal at all essential war plants.

In order to control the distribution of coal to domestic consumers and industrial plants by retail dealers, the dealers will be required to make a special report to the State Fuel Administrators and from these reports deliveries to manufacturing plants not on preference list can be curtailed when necessary.

Under this plan of distribution each consumer should arrange for shipments from the same source of supply as last year, if possible. If diversion of coal for the war program, or the zoning system will not permit this, the consumer should make every effort to form new connections, preferably under a contract arrangement, wherever a supply is available, before calling on the State Fuel Administration.

# Prospects of a Chemical Industry in Southern California\*

The Possibilities of the Development of the Deposits of Lignite and Desert Alkali into Sources for the Production of the Fundamental Chemicals

By JULIUS KOEBIG

IN DISCUSSING the prospects of a chemical industry, it is essential to define the scope of the term. We have many smaller and larger plants on the Coast which we call chemical factories and of which we are accustomed to boast at home and abroad, but we have only a few whose name and importance are more than of local interest. The principal exceptions are in the manufacture of sulphuric acid, super-phosphates, explosives, soap, Portland cement, beet sugar, leather, and the refining of crude oil. They are in a flourishing condition wherever they are not unduly capitalized, and where the management expects to earn its profits from the earnings of the plant rather than from the manipulation of the capital stock. The basis of their success is:

(1) Abundance of suitable raw material at a cost comparing favorably with the cost of raw material in competing centers of the respective industries.

(2) Adequate local facilities for manufacturing and transportation.

(3) Home market for the product and opportunity to extend the market within a reasonable radius.

(4) Last, but not least, skillful management capable of modifying manufacturing methods according to local conditions and of improving constantly on such methods, both with regard to cost and quality of product.

Every one of the established plants, be they small or large, together with almost every industrial enterprise on the Coast, is at present under the disadvantage of the high cost of heavy chemicals. Many others are out of the question, because of this high cost of heavy chemicals. Without a home production of heavy chemicals, at prices not much higher than they can be produced in other centers of industrial activity, it is useless to expect the development of a chemical industry. This, however, demands large capital, enterprise and efficiency.

It is my purpose to place before you the possibilities in Southern California which justify the investment.

The vast chemical industries in Germany, France and England started from the manufacture of cheap soda, and still base their success on this product.

The manufacture of cheap soda is the very life blood of the rapidly increasing chemical industries of the East. Unless we are able to produce cheap soda, it is useless to try and build up a chemical industry.

Before closing these introductory remarks, permit me to give you some of my own personal experiences. When I was Assistant Professor of Chemistry at Strassburg, a gentleman called on me and asked if I would enter his employ for the purpose of developing an aniline dye-works. I told him that I had no experience in the manufacture of dyes. He replied that he wanted a chemist, the practical part would subsequently take care

of itself. When I resigned, after three years, we had over three hundred men in our employ; we had some fourteen chemists directing the work in the factory; I had a research laboratory in which from ten to twelve chemists were constantly at work on the development of new products and processes; and the factory paid from 80 to 250 per cent dividends each year.

On a trip across the Atlantic, I made the acquaintance of a gentleman heavily interested in an illuminating gas works in one of our largest cities. In discussing the possibility of utilizing his coal tar to better advantage than selling it at low prices for export, I advised him that the first step must necessarily be the erection of a tar refinery. He sent an engineer to England to copy the equipment of a prosperous tar refinery there. He bought, at high cost, the recipes used there, and hired a foreman in their service. He employed a chemist, not for running the factory, but for finding out whether there were differences in the guaranteed strength of acids, etc., which he bought. The refinery never was a success. After a few months an explosion occurred and the plant burned up. The typical differences between these two views is that of success and failure.

## THE NECESSITY OF INORGANIC INTERMEDIATES

The fundamental requirements for a successful development of a chemical industry are:

Cheap acids,  
Cheap soda,  
Cheap fuel and  
Cheap power,

to which has to be added cheap iron for machinery and apparatus.

Without these, and all of these, chemical works are doomed to remain of secondary importance. All they can hope to accomplish is the refining of half-finished products. The life of such industries, no matter how profitable they may be from the start, can only be a limited one. It is only a question of time before the consumer will learn to use the half finished product or to do his own refining, thereby cutting out the refiner's profit. One example will suffice to illustrate this fact. Establishments in this state, which carried the proud name of soda manufacturers, bought soda-ash and caustic soda in Europe or later on in the East. They produced sal soda and lye in small packages for the use of soap manufacturers and others, in addition to supplying the household trade. Some of these factories grew to considerable proportions. But today they are reduced to the level of retailers, while the consumers buy their supplies directly from the real manufacturers of soda.

These refiners, however, served a well-defined economical want in the early days of the development of our State. At that time the market for any kind of com-

\*Read before the Los Angeles Section of the American Chemical Society.

modity was small. We had few consumers of chemicals, or any other kind of merchandise for that matter, whose wants justified the purchase of needed supplies in lots sufficiently large to obtain reasonable freight rates. We then were tagged away in splendid isolation in the remotest corner of civilization. Our sturdy pioneers thought little of the cost of living and had less demand for manufactured articles. They had to and did employ their spendid energy and every available dollar at their command for the purpose of turning our state from almost half savagery into a fit place for human habitation and the pursuit of happiness. How well they have succeeded, we all know. In addition our railroads and the Panama Canal have changed our location from an isolated spot to almost the center of the coming commercial development, which is bound to have the countries bordering the Pacific as a stage. This shifting of the commercial situation, our large and rapidly increasing population, the development of our mines and agriculture, all make insistent demands for our industrial chemical development. Our mines need heavy chemicals for the reduction of their ores. Our fields and orchards need fertilizers for assuring their continued fertility. Our agricultural industries need chemicals again for manufacturing our agricultural products into staple articles. Our animal industry, our tanneries, our soap makers are handicapped on account of the high prices of chemicals. Our oil refiners offer a large market for soda products. These and many other industries already established offer an alluring market for the products of a general chemical industry, so that there can be no possible question of a market. This alone, however, is not sufficient. We must have the raw materials and manufacturing facilities required to secure a profitable production which will put us on a square, even footing with the centers of industrial activity now furnishing the products needed, so that we can rely upon our ability to retain our home markets for our home products against the keenest competition. It is my endeavor to show in how far our available raw materials justify us to advocate a general chemical industry under the local conditions.

In the manufacture of sulphuric acid we have already made a long step forward. Both the lead chamber and the contact processes are in successful operation on an even footing with other states and countries. Sulphur and pyrites are readily obtainable here. Our metallurgical works furnish us a never-ending supply of sulphur dioxide from their roasting furnaces, which is now mostly used in the production of by-product sulphuric acid. In conjunction with this sulphuric acid, muriatic and nitric acids could be manufactured; the former from our large salt deposits, and the latter from Chilean nitre, which is as economically obtainable here as in the East; however, we would be under great disadvantages at present, because our market for salt cake is very limited.

#### THE SODA INDUSTRY

In the alkali industry, conditions are decidedly different. At present, we have none. In order to ascertain whether such an industry is possible in Southern California, I must ask you to follow me in a short review of its history and its present status.

Perhaps the most epoch-making progress in the

chemical industry during the last 150 years was the Leblanc soda process. In England, where it found its first home and received its most essential development, it reduced the price of soda-crystals from \$300 per ton in 1814 to \$13 per ton in 1896. Its principle is a very simple one. In its first phase common salt is decomposed by the aid of sulphuric acid into sulphate of soda, commonly called salt-cake and hydrochloric acid. In its second phase the salt-cake is treated in the black-ash furnace with limestone and coal. The resulting black-ash consists essentially of sodium carbonate and insoluble calcium mono-sulphide. By leaching the soda is brought into solution. The remaining calcium sulphide forms the alkali maker's waste. As long as the factories were few and of small capacity, the muriatic acid was allowed to escape and the waste, a bad malodorous nuisance, was dumped into the ocean. But soon it became necessary to recover the muriatic acid and also to find some way of utilizing the waste. The one was accomplished largely by the manufacture of bleaching powder, the other by the ingenious chance process which recovers the sulphur and lime from the waste.

The second method for the manufacture of soda-ash is the Solvay ammonia-soda process. Its raw materials are salt-brine, ammonia and limestone. A properly proportioned mixture of salt-brine and ammonia is made which is treated with carbon dioxide. The bicarbonate of soda separates as crystals and is filtered dry. The filtrate contains ammonium chloride from which the ammonia is recovered by distillation of the limed mother liquid.

The third is the electrolytic process, in which the salt brine is decomposed by the electric current and chlorine gas and caustic soda produced.

Many other methods have been proposed. They, however, have either proven to be impractical or only of secondary importance like the manufacture of soda from cryolite.

The Leblanc process today has been almost entirely abandoned in favor of the ammonia process. The enormous factories in England and on the European continent have either gone out of existence or changed to the cheaper Solvay method. The reasons for such change are obvious. In the first place, it is necessary for the economical handling of the Leblanc process to combine under one roof the manufacture of sulphuric acid, sulphate of soda and the final black-ash, which requires an enormous outlay for first installation as compared with the Solvay or electrolytic processes. Then again it is much cheaper to produce and handle the large tonnage of salt in the form of brine than it can possibly be in the form of dry salt. And last but not least, the vast amount of muriatic acid, requiring heavy, expensive and costly apparatus for its recovery, does not find a ready and profitable market, either as acid or in the form of bleach.

#### SOURCE OF SODA FROM THE DESERT ALKALI

In considering the development of the alkali industry in California, we have therefore apparently only a choice between the Solvay and the electrolytic processes. Unfortunately neither of them is adapted to our present conditions. Except in the condensed sea water, we have no sources of the brine required as the starting point. Even the sea salt works, using solar evaporation, can-

not begin to furnish brine of proper concentration at anything like the cost of the brine produced from the salt beds of New York, Michigan and other states. To dissolve the salt from our desert deposits is far too expensive. Our gas works use oil for the production of illuminating gas and therefore cannot supply a prospective Solvay soda works with the necessary large supply of cheap ammonia. The cost of electricity from our hydro-electric installations is much too high for the use in the electrolytic process. Finally, we have no adequate market for the large quantity of calcium chloride of the Solvay process nor for the chlorine of the electrolytic process. This leaves us in the deplorable condition of having to develop some new and untried method, if we wish to start the very foundation of a general chemical industry. But fortunately, nature itself holds out the solution of the problem, characteristic only to our arid regions, in our desert alkalies. We have some deposits of very great magnitude which consist of sulphate of soda of as great or greater purity than the best salt-cake manufactured in the first phase of the Leblanc process. It is possible to mine and ship this sulphate to a convenient factory site at a cost considerably less than \$5 per ton. By using this natural salt-cake in the second phase of the Leblanc process, we do not only find a manufacturing method in the perfection of which, in all its details, hundreds of the best chemical engineers have worked for nearly a century, but we also omit all the unfavorable features, which resulted in its decline in competition with the Solvay process. The required capital for its installation is reduced to one-half or one-third by the omission of the costly apparatus for the manufacture of sulphuric acid and the conversion of salt into salt-cake in the first phase of the process. The great disadvantage of producing the enormous quantities of muriatic acid, for which we have no market, is entirely done away with. The only by-products are sulphur and carbonate of lime, of which the latter goes back to the black-ash furnace. Since nature has done, for our arid regions, the most costly part by offering the natural salt-cake as a raw product, it has given us an opportunity to revive the Leblanc process in a manner possible only and eminently characteristic in this part of the United States.

A careful calculation of the cost of production of soda-ash, using oil or producer gas as fuel, and taking \$5 per ton as the value of salt-cake delivered at the factory, results in a cost price of not to exceed \$10 per ton or 96 per cent soda-ash. It is hardly possible to over-estimate the immediate influence which the reduction of the cost of soda-ash to one-half of its present price will have in stimulating our already existing industries. Since it would at once put us on an even footing with the centers of the chemical industry in this country and abroad, it would enable us to manufacture our own cyanide for mines and orchards as well as permit the home production of a large line of fine chemicals. Last but not least, we could in time not only supply our home markets, but enter the export trade with a certainty of being able to hold our own against the keenest competition.

In close relation to the alkali industry stands the manufacture of potash salts. The prospects of its development on the Coast are certainly bright ones. The problems involved in the extraction of potash from kelp,

alunite and some favored desert deposits are at present under serious consideration. I have no doubt that they will be favorably solved in due time. The necessity, however, of utilizing all by-products, for a permanent commercial success, imperatively points to the establishment of a general chemical industry to take care of them. I am inclined to believe that both are so vitally dependent upon each other as to venture the assertion that together they are bound to succeed, while singly, the potash industry may fall far short of the sanguine expectations.

In considering the fuel situation, we are in the fortunate position of being able to meet all demands with a considerable margin in our favor. Our fuel oils furnish an excellent and economical fuel for all manufacturing purposes. It is only to be regretted that some of our best oilfields have passed into the control of other than American interests. The development of the refining industry is gaining larger proportions every year, which necessarily means increasing market for chemicals. One of the principal demands will be for cheaper soda products. In the refining of our crude oils, there are many phases of utilizing all possible by-products, which will have to await a general chemical industry for their ultimate commercial success.

#### LIGNITES AS A SOURCE OF GAS, TAR AND AMMONIA

In the lignites, of which a few large deposits exist in our state, another source of fuel is available. It is a matter of general knowledge that this coal cannot compete with the cheaper and more economical crude oil as a fuel for manufacturing purposes. The value of our lignites, however, are very large indeed, if we consider them in the light of a raw material for a chemical manufacturing industry. With the aid of producer furnaces and gas engines, our lignites are able to produce electric power even at a less cost than the average of our hydro-electric plants. In the by-product producer furnace, the lignites will give us an important source of ammonia and coal tar besides the electric power. The by-product coke oven adds to these a very serviceable coke for many purposes. The results obtained by me in an elaborate research on this subject are eminently satisfactory. I cannot forego the opportunity of stating a few of them.

Cost of electricity produced from lignite at the pit mouth with producer furnace and large unit gas engines.

#### ELECTRIC POWER PRODUCED FROM LIGNITE

|                                                                               |          |
|-------------------------------------------------------------------------------|----------|
| Cost of installation per kw. ....                                             | \$100 00 |
| Cost of production per kw.-hr., including 16% fixed charges on capital, ..... | 45       |

#### PRODUCTS FROM 1 TON LIGNITE IF USED IN BY-PRODUCT

| Coke Oven                                            |        |
|------------------------------------------------------|--------|
| 872 hp.-hr., valued at 1 cent. ....                  | \$4 36 |
| 60 gallons of tar valued at 3 cents .....            | 1 80   |
| 70 lb. ammonium sulphate valued at 3 1/2 cents ..... | 2 45   |
| 800 lb. of coke valued at \$2 30 per ton .....       | 1 00   |
| Total .....                                          | \$9 61 |

If you consider that the value of lignite at the pit mouth does not exceed \$1 per ton and that the total cost of operating such a plant is not more than \$2 per ton, these figures need no further explanation.

The coke obtained from our lignites certainly is not of a quality adapted to the operation of blast furnaces. But my as yet incomplete research work has resulted in showing a way, by which I feel positive first-class blast furnace coke can be manufactured from at least

some of our lignite deposits. This coke, however, is an ideal raw material for the manufacture of calcium carbide and calcium cyanimide. In the production of this coke not only sufficient by-products are obtained to pay most, if not all, of the costs of operating the plant, but a large source of electric power becomes available at a cost much lower than it could be bought from our hydroelectric installations. Calcium cyanamide as a fertilizer offers a practically unlimited market which cannot be overstocked for a good while to come. The ease with which it can be used in an endless number of reactions in the manufacture of organic chemicals is well known. Next to the all-important soda-industry, this utilization of our lignites appears to be the industrial development with the most brilliant future.

The tar from the producer furnace or coke oven has a well-established market value. It can, however, well be used in a tar-refinery, producing not only the more commonly known tar products such as phenols, pitch, etc., but also the cyclic hydro-carbons, viz., benzol, toluol, cresol, naphthaline, anthracene, etc., which opens the long vista of synthetic coal-tar products culminating in an aniline dye industry.

The last requirement for a successful industrial development, cheap iron for our apparatus and machinery we do not have, at least not now. We have large deposits of excellent iron ores, but we lack the all-important supply of cheap coke. All attempts to use liquid or gaseous fuel instead have not as yet proven successful, nor will they ever do so in my opinion. I have stated above that my researches make it seem probable that good coke will finally be obtained from some of our lignites, but this remains to be proven. All we can hope for at present is the successful development of the reduction of iron ores in the electric furnace, which we can very materially assist by a probable reduction of the cost of electric power by using our lignites as outlined above.

In my discussion, I have deliberately refrained from advocating any industrial development, for the success of which our raw-materials, available markets and local conditions do not only promise a highly remunerative investment at the present prices of like manufactured products, but also place us on an even footing with the industrial centers of the world, thereby enabling us to command our share of export trade. In addition, I have only advocated well-known and tried methods. No new and untried inventions or secret processes are required for our success. True, we must not expect success by using iron-clad method or recipes, which have been elaborated for other local conditions than our own. We must benefit by the experience of Europe and our own Eastern States and intelligently adapt their methods for our use.

I certainly am aware of the difficulties in the way of making California the home of a large and prosperous chemical industry. Our investors are generally not familiar with the nature and vast possibilities. There is a tremendous amount of educational work to be done before we can hope for a substantial success. On many occasions, I hear the candid opinion that for the purpose of chemical industrial pursuits, it is necessary to import a German, French, English, etc., chemist. This is by no means the case. Our American chemists are second to none. The only thing lacking is that our

investors are surely excellent judges of engineers, bookkeepers, skilled and unskilled workmen, but they fail to realize the fact that chemists are representative of just such an exact science as the civil engineer. We are too often considered to be no more or no less than a visionary drug clerk or an uncanny trance-medium. Many of our manufacturers would rather spend a fortune on a misty secret-process than pay an adequate remuneration to a competent chemist. We must combat most energetically this erroneous idea. Let us all stand together to emphasize and insist upon a realization of the fact that a chemist is not only an analyst but a very important factor in the general industrial development and the one paramount factor in the chemical industry.

If we succeed, if we create a soda industry utilizing our deposits of alkalies, if we start the use of our lignites as a raw product for the cyanamide and coal tar industry, if we assist in finding ways and means to reduce our iron ores, then we shall realize that our State is not only capable of producing its own chemical products, but is in some directions even more favored than other industrial centers. Instead of being the last outpost of civilization, California, through the shifting of the world's activities and the completion of the Panama canal, has become a center for the world trade highways. Nothing can do so much in making it a center in the industrial world as the development of a large and varied chemical industry. We have all the favorable conditions required and it rests primarily with us to realize them. In this effort, I ask for your hearty coöperation, as well as the coöperation of our colleges and manufacturers.

Los Angeles, Calif.

## The Future of Electrochemistry and Metallurgy on the Pacific Coast\*

By J. W. BECKMAN

I BELIEVE the Pacific Coast holds a better future for the manufacture of electrochemical and electro-metallurgical products than most parts of the world. This opinion is formulated after having traveled through Europe all the way from northern Sweden and Norway down to the southern part of Italy, visiting electrochemical centers.

These electrochemical centers are located where engineering skill finds that hydroelectric power can be developed at a reasonable price and where raw materials can be obtained readily. There are electrochemical plants in Norway north of the Arctic circle. The only access to those plants is by water route; the raw material is brought in from all parts of the world by boat and the finished products are shipped out from these plants by water. You could find conditions of a similar nature in most electrochemical centers of Europe. The primary factor is cheap power; availability of raw material is secondary, while the proximity to markets for their products as a rule is the third factor. We, on the Pacific Coast, are blessed by an abundance of water power, much of which can be developed at a very low figure provided sound and wholesome financing is done. We have on the Pacific Coast

\*Extracts from a paper read May 24, 1918, before the American Institute of Electrical Engineers. Author is president, Beckman & Linden Engineering Corporation, San Francisco.

large mineral resources, some of them practically untouched as yet, suitable for electrochemical or electrometallurgical manufacture. We have in Alaska situations identical with those on the coast of Norway, where power can be obtained at low figures on tidewater. We have stupendous opportunities on the Columbia River in Washington and we have the possibility of power developments all through the Southern Sierras.

In Europe, installations as small as a few hundred horsepower are used for electrochemical industries, and the day will come in California and the Pacific Coast, when we will find electrochemical industries located all through our mountains, where water powers even of small dimensions are available.

The quicker electrical engineers can realize that the big consumers of hydroelectric power are the electrochemical industries the better. The quicker the California hydroelectric development can realize that the day of the public service plant has passed for them the better. Future developments of the water powers of California and the Pacific Coast are not to be made for the lighting of dwellings and running of street cars, but for the industrial development of the state and to some extent for the operating of the railroads of the country.

#### ELECTROCHEMICAL INDUSTRY A GOOD POWER CONSUMER

Without any question the best consumer that any power producer can have is an electrochemical or electrometallurgical industry. They run on a power factor 90 per cent and better and as close as possible to a 100 per cent load factor. They run day and night the year around. The electric furnace load is a larger load than the electrolytic load. The largest electrolytic plant in the United States, I believe, takes about 10,000 kw., while the largest electric furnace plant in the United States absorbs 150,000 kw. The electric furnace load is built up by a few large units, while the electrolytic load is built up by a great number of small units.

We have as yet only a few electrochemical and electrometallurgical industries on the Pacific Coast. We have a few electric steel furnaces, but I think we have made a fair beginning and the opportunities are standing wide open. With the shortage of power in the East and with the increased demand for electrochemical products that not only exists today but will continue to exist, the future holds big opportunities in my estimation, along electrochemical and electrometallurgical lines for the coast states. We need badly a basic industry—such as iron production—but we hold in our hands all the essentials for a pig-iron industry similar to that of Sweden. Swedish iron is known all over the world with highest regard. California iron could be equally well known and equally well spoken of. We have enormous iron deposits—there is scarcely a county in this state that does not contain iron deposits and there are a number of them that have very large deposits of high-grade iron ore. For instance there is one deposit which is estimated to contain about 250,000,000 tons of 65 per cent ore.

Sweden reduces its ores by means of charcoal, made incidental to their lumber mill operations. It is produced either in by-product charcoal ovens or by heap charcoaling. The Pacific Coast holds more timber than Sweden and Norway combined, but charcoal is a scarce

commodity here. Therefore, to be able to develop an iron industry, it is essential that the timber and wood-working industries co-operate in producing charcoal.

#### ELECTRICITY REPLACING CHARCOAL IN SWEDEN

The electric shaft furnace is a complete success in Sweden. Every charcoal furnace that goes down for reconstruction is replaced by an electric shaft furnace; due primarily to the fact that one ton of charcoal will produce three tons of pig iron in an electric furnace, where before it produced only one ton in a charcoal furnace. The iron industry of Sweden is located in the very heart of Sweden, distant from the seaboard, and in a very limited area.

We have had unfortunate experiences in California in all attempts at making pig iron, but with the experience gained in Sweden we should be able to manufacture pig iron successfully for the needs of our present and future industries. The power necessary for this is available in large quantities in this state waiting to be developed. Blast furnaces are now being built in Sweden, taking up to 10,000 hp., and a few of these installed in this state would quickly show their influence in the metal markets.

The manufacture of electric steel is another industry which is needed here in conjunction with the pig-iron industry.

#### NITROGEN FIXATION A LARGE FIELD

Another big field for the development of electrochemistry and the power of this state is in the artificial fertilizer field. There are large stretches, as I understand it, of the valleys of California that contain excellent soil conditions and would be fertile fields, provided nitrogen in the shape of some fertilizer could be supplied them. Air is available everywhere, hydroelectric power can be developed at many points and at very low cost. We can either fix atmospheric nitrogen in the shape of nitrate or we can fix it in the shape of cyanamide, a large supply of lime rock is available and cyanamide answers many times as a fertilizer as well as nitrate.

In mentioning these developments I believe I have given the most important electrochemical industries suitable for large power developments. We have a large possible field for minor industries in the manufacture of alloys and chemicals. Many of these naturally are dependent on their possible market outlet, and I believe it is an important thing to remember on the Pacific Coast that our legitimate market, on which we should spend our efforts for the selling of our products, are not east of here, but west of here. The big industrial developments of the future are going to take place in China, Japan, Australia, and the countries south of us. We have golden opportunities there and the quicker we realize it the greater will our results be.

There is a tendency, and I want to warn you against it, for the Easterners and Eastern interests to say that it is impossible for us to accomplish such things in the West. It is a very natural, conservative tendency of people not acquainted with localities to make such judgments, but the important thing for us is to compare our resources with those of other localities on the globe where things have been accomplished in spite of handi-

caps. I am especially referring to the Scandinavian countries. Sweden and Norway are to-day factors—large factors—in the electrochemical field in spite of being handicapped by a lack of raw material and by distant markets. Another thing we have to bear in mind is that no industry was great before it was small. The only thing to do to build up the Pacific Coast's electrochemical industries is to copy what was done elsewhere; start them in a small way and gradually build them up to large ones. This, in turn, can only be accomplished by a close co-operation of electrical engineers and chemists of the Pacific Coast.

San Francisco, California.

## The Evaluation of Zinc Dust: A Proposed Method of Analysis\*

BY L. A. WILSON.

**Z**INC dust, or "blue powder," as it is commonly known, is being used in constantly increasing amounts for organic reductions, sherardizing, precipitation of gold and silver in cyanide practice, and in certain classes of paint.

Due to the demands of the trade for a material superior to the ordinary spelter furnace blue powder, the zinc dust sold to-day is largely a specially prepared product. The two particular qualities usually demanded by the consumers of zinc dust are fineness and high metallic zinc content.

The fineness is best determined by microscopical examination, but as usually carried out in practice, it is a simple matter of careful screening a sample through a nest of screens. On the other hand, the determination of the metallic zinc content, or reducing power as metallic zinc, is not so easily obtained and determinations by different methods or even by the same method with different analysts will show considerable variations. Since the manufacturer analyzes his product to maintain the grade, and the consumer is likely to analyze the zinc dust which he buys to preclude against accepting inferior material, there is need for a standard method that may be followed without great detail and which will obviate the misunderstanding originating from variant analyses. It is the purpose of this paper to cover only the determination of the metallic zinc contents of zinc dust, and not its physical properties.

### HYDROGEN EVOLUTION METHOD ADOPTED

After experimenting with the various proposed methods, the hydrogen evolution method was adopted because it was found to give the most consistently accurate results. The method and apparatus to be described later are the outcome of experimental work extending over several years, starting with the apparatus proposed by Franz Meyer and adding improvements and modifications as the work progressed. The method and apparatus have been used for hundreds of determinations for metallic zinc in zinc dust, and have given more accurate results than any method described in literature. For this reason they are proposed as a standard means for determining the metallic zinc contents of zinc dust.

The procedure and apparatus recommended for this method are fundamentally the same as in the Franz Meyer method.<sup>1</sup> By re-arrangement of apparatus and improvements in details of the procedure, the accuracy of determining the metallic zinc content of zinc dusts has been raised and the time required materially shortened. The average time required for high-grade zinc dust of which 90 to 95 per cent passes a 350-mesh sieve, and contains less than 0.3 per cent of metallic impurities, is about 1½ hours, against 2 to 4 hours with the Franz Meyer apparatus. With the latter apparatus there is no satisfactory way to speed up the determination, shaking being only mildly effective. In the proposed new method, the addition of strong acid accomplishes this purpose.

The method and apparatus may be best described with the aid of Fig. 1. A 1-g. sample of zinc dust is weighed and transferred as rapidly as possible to a small Erlenmeyer flask A, of 100 or 200-cc. capacity, in which is placed a piece of sheet platinum about 1.5 cm. square. About 5 g. of clean unoxidized ferrous sulphate crystals are added on top of the zinc dust and the flask nearly filled with distilled water saturated at room temperature with hydrogen gas. The object of adding the sheet platinum and ferrous sulfate is to increase the rate of hydrogen evolution by catalytic action.

FIG. 1—APPARATUS FOR EVALUATION OF ZINC DUST

A further reason for adding the ferrous sulphate on top of the zinc dust sample is to coagulate the latter as much as possible when it becomes wetted, and thus prevent the floating of more than an unappreciable amount of the sample.

The rubber stopper containing separatory funnel B and connecting tube C is tightly inserted into the neck of the flask. A little distilled water is poured into B and the three-way stopcock in C turned to connect the flask with the downward outlet. Enough water is now run in from the separatory funnel to displace all the air in the flask and the connecting tube through the bore in its stopcock. The stopcock in C is now turned so that the downward outlet is in connection with the measuring tube D. By raising the leveling bottle E, containing 10 per cent sulphuric acid also saturated with hydrogen at room temperature, all the gas in D is displaced. The stopcock in C is now turned through 90 deg., so as to connect the decomposing flask A with the measuring tube D. The system is hence completely filled with liquid and ready for the generation of hydrogen. The measuring tube D has a total capacity of 400 cc. and is graduated from 250 to 400 cc. by 0.25 cc.

\*Excerpt of a paper, subject to correction and modification, presented at the Twenty-First Annual Meeting of the Amer. Soc. for Testing Materials, Atlantic City, N. J., June 25-28, 1918.

<sup>1</sup>Scott's "Standard Methods of Chemical Analysis"

Thirty cubic centimeters of 1:1 sulphuric acid are now poured into the separatory funnel. A small portion of this acid is allowed to run into the decomposing flask until a brisk but not too rapid evolution of hydrogen takes place. The acid, being much heavier than water, settles to the bottom of the flask and the action commences immediately. The gas evolved, together with some solution and a very small amount of zinc dust passes over into the measuring tube, displacing the acid there. When the action in the decomposing flask has slowed down, more strong acid is introduced until all has been added. During this time the acid in the measuring tube and flask is shaken so as to wash down the particles of zinc dust from the upper parts of the flask and tube now filled with gas. The particles in the measuring tube on coming in contact with the 10 per cent sulphuric acid are readily dissolved and generate their portion of hydrogen.

When all the zinc dust has been dissolved, water is run in from the separatory funnel to force the hydrogen over into the measuring tube and to fill the flask and connecting tube with water through to the stopcock *F*, which is then closed. After leveling with the leveling bottle the volume of hydrogen generated from the 1-g. sample at the prevailing atmospheric conditions is read from the measuring tube. The percentage of metallic zinc in the sample is then calculated from the following expression:

$$\text{Per cent of metallic zinc} = \frac{V \cdot (P - p) \times 0.29196}{(1 - 0.00367t) 760}$$

in which *V* = volume of gas in measuring tube at atmospheric conditions, *P* = barometric pressure, *p* = vapor tension of water above 10 per cent sulphuric acid at room temperature, and *t* = room temperature.

**Necessary Precautions.**—To obtain results of the highest accuracy, it is necessary when weighing out samples of zinc dust which are very finely divided, to keep the time of exposure as small as possible in order to minimize the oxidation that takes place with the oxygen of the air. It is also highly important when samples are to be held, that they be kept in ground glass stoppered bottles, completely filled, and sealed with paraffin or wax.

The two variables most likely to affect the results are temperature and barometric pressure. A change in the barometric pressure is practically always extended over a reasonable length of time. A careful reading of the barometer when the volume of gas in the measuring tube is read will eliminate any error from this source. A temperature change, on the other hand, affects not only the volume of gas, according to Boyle's law, but also affects the vapor tension of water and hence the actual pressure on the hydrogen when measured. Unlike barometric variations, changes in temperature can to a large extent be avoided by making the analyses in a room maintained at a nearly constant temperature, enclosing the apparatus in a cabinet, with door fronts that are opened only when measurements

are to be taken, and keeping all water and acid saturated with hydrogen in the same cabinet.

The rubber connection between the connecting and measuring tubes must be of heavy rubber and should be shellacked.

#### APPARATUS FOR CORRECTING TO STANDARD CONDITIONS DIRECTLY

Where a large number of metallic zinc determinations are carried out daily, the matter of calculating the results becomes laborious and is occasionally a point of error. This can be done away with in a simple manner.

A measuring tube, similar to the one used for measuring the gas, is sealed at the top below its stopcock filled with mercury and placed in a glass cylinder containing mercury.

Hydrogen, perfectly dry, is now introduced until it fills less than half the graduated stem of the tube. After leveling, this volume is read very accurately together with the room temperature and pressure. As a check, this volume may be read at another temperature. The volume is calculated to standard conditions. Enough pure water is now introduced into the measuring tube to entirely cover the mercury. After equilibrium has been attained, the volume temperature, and pressure are read and the dry volume of hydrogen calculated will check with the original volume introduced. Fig. 2 shows this apparatus in readiness for use.

The volume of gas in this tube will vary according to atmospheric conditions, but since the volume of dry gas at standard conditions is known, the factor to correct the volume of hydrogen gas evolved in a determination to standard conditions is a simple matter of calculation, as given by the following expression:

$$\text{Per cent of metallic zinc} = \frac{V_D \cdot v_s \cdot 0.29196}{v_d}$$

in which *V<sub>D</sub>* = volume of gas evolved in determination, *v<sub>s</sub>* = volume of dry hydrogen in correction tube reduced to standard conditions, and *v<sub>d</sub>* = volume of hydrogen in the correction tube read at the same time as *V<sub>D</sub>*.

Where the amount of work carried out would warrant it, a table may be made up giving the factor for each graduation on the tube. The factor is the calculated result of  $\frac{v_s}{v_d} \times 0.29196$ , where *v<sub>d</sub>* is the volume for

each graduation. We can now directly convert the gas volume in the measuring tube after each determination directly over into percentage of metallic zinc.

The vapor tension of water is slightly lower above 10 per cent sulphuric acid than above pure water, and the error that would be introduced by taking the volumes in the correction tube directly would give results ordinarily about 0.3 per cent low.

The table of factors calculated is corrected to take this into account. This difference is indicated in Fig. 3, which shows the curves of vapor tension of water above pure water and dilute sulphuric acid plotted against temperature. The curves are for the following:

*A* = Vapor tension above pure water;

*B* = Vapor tension above sulphuric acid containing 10.89 g. H<sub>2</sub>SO<sub>4</sub> and 100 cc. water;

*C* = Vapor tension above sulphuric acid containing 18.4 g. H<sub>2</sub>SO<sub>4</sub> and 100 cc. water. This solution is 10 per cent H<sub>2</sub>SO<sub>4</sub> by volume and the curve was obtained by interpolation, using curves *B* and *D*;

FIG. 2  
CORRECTION  
TUBE.

$D$  = Vapor tension above sulphuric acid containing 32.02 g.  $H_2SO_4$  and 100 cc. water.

It will be seen from curves  $A$  and  $C$  that where the temperature changes over a large range the use of a correction tube will give slightly erroneous results, due to the increasing difference in vapor tension above water and 10 per cent sulphuric acid with increasing temperature. In this case, results should be calculated, using

FIG. 3. Vapor Tension of Water above Pure and Dilute Sulphuric Acid. Data for curves A, B and D from Landolt-Bernstein, page 167. Curve C interpolated.

the elementary formula. Where the laboratory temperature is controlled, the correction tube gives satisfactory results and is a valuable additional piece of apparatus.

In this proposed method all known possibilities of error have been taken into account and accurate reproducible results are obtained. The results of many analyses extending over a long period of time, and the running of many check samples as unknowns, have confirmed this and prompt the putting forward of this method and apparatus as a standard means for determining the metallic zinc content of zinc dust.

Gold exports from the United States during eleven months of the fiscal year ending June 30 have exceeded imports by \$95,000,000. This, as it happens, is the largest net export in the country's history and compares with \$661,000,000 excess of gold imports in the same period a year ago.

## Government Badly Needs Trained Men

With a perfect organization at home for producing the material of war, victory will be easier. The actual fighting forces must have the constant support of a host of highly trained experts if the nation's greatest undertaking is soon to be successful. The United States Civil Service Commission, whose duty it is to recruit the civilian army, announces that right now the civilian branches of the Army and Navy are in urgent need of thousands of technical men to work in direct connection with the prosecution of the war.

Among the positions now open are the following:

|                                                               | Usual entrance salary     |
|---------------------------------------------------------------|---------------------------|
| Metallurgist .....                                            | \$3,000 a year            |
| Assistant chemist and metallurgist .....                      | \$2,000 a year            |
| Metallurgical chemist .....                                   | \$1,600 to \$2,400 a year |
| Assistant metallurgical chemist .....                         | \$1,000 to \$1,600 a year |
| Metallographist .....                                         | \$1,500 to \$2,000 a year |
| Assistant chemist .....                                       | \$1,800 to \$2,000 a year |
| Junior chemist .....                                          | \$1,200 to \$1,440 a year |
| Powder and explosives chemist .....                           | \$1,600 to \$2,400 a year |
| Assistant powder and explosives chemist .....                 | \$1,000 to \$1,600 a year |
| Chemical engineer .....                                       | \$1,600 to \$6,000 a year |
| Assistant chemical engineer .....                             | \$1,200 to \$1,600 a year |
| Superintendent of high explosive and acid plant .....         | \$1,500 to \$1,800 a year |
| Laboratory aid .....                                          | \$4.00 a day              |
| Tolul expert .....                                            | \$1,800 to \$3,000 a year |
| Operative in gas manufacture .....                            | \$1,600 to \$2,400 a year |
| Assistant operative in gas manufacture .....                  | \$3.00 to \$5.00 a day    |
| Superintendent of nitrate and chemical plants .....           | \$2,400 to \$6,000 a year |
| Assistant superintendent of nitrate and chemical plants ..... | \$1,600 to \$2,400 a year |
| Engineering draftsman .....                                   | \$3.04 to \$7.04 a day    |
| Mechanical draftsman .....                                    | \$4.00 to \$8.00 a day    |
| Apprentice draftsman .....                                    | \$4.80 a year             |
| Metal furniture draftsman .....                               | \$4.00 to \$6.00 a day    |

A further long list of technical positions in the War, Navy, and other departments are to be filled. For the positions named applicants are not required to report at any place for examination, but are rated upon their education, training, and experience, and in some cases on work submitted with the application. Physical ability is also considered in some instances. Ratings are arrived at from information set out in the application blank and from corroborative evidence.

The Civil Service Commission calls particular attention to the fact that all necessary information concerning civil service positions, and application blanks therefor, may be obtained free of any cost by applying to the Commission's representative at the post office in any important city, or by addressing "The United States Civil Service Commission, Washington, D. C." Positions of junior chemist and many of the drafting positions are open to women.

## Chicago Men Unite for War Work

A score of the leading Chicago Engineering and Technical Societies have organized a Joint War Committee: Chairman, F. K. COPELAND; Vice-Chairman, W. L. ABBOTT; Treasurer, W. A. FOX; Secretary, E. S. NETHERALT, 1735 Monadnock Block, Chicago, Ill.

Board—WM. HOSKINS, C. A. KELLER, C. E. LORD, C. F. LOWETH, I. RANDOLPH and R. S. SCHMIDT.

The purpose of this organization is to get the various technical men together and combine their individual efforts in rendering any aid of value in scientific work, pertaining to the war.

# The Possibilities of Powdered Coal as Shown by Its Combustion Characteristics\*

An Exposition of the Merits of Powered Coal Based on Its Efficiency and Flexibility to Meet Varying Demands—Advantages of One-Stage Combustion—Importance of Thorough Mixing

BY W. G. WILCOX

INDUSTRIAL efficiency and the smooth operation of the machinery of industry require continuous supplies of power, materials and labor. These are of equal importance in that the lack of any one of these is equally disastrous.

The wonderful work being done by women in Great Britain and France shows us that we also have great reserves of labor hitherto unsuspected and as yet practically undeveloped. When we regard the percentage of available men put in the field by both France and Great Britain—when we know that their industrial production is nevertheless carried on today at a high peak due to the utilization of women in industry, we can rest assured that the solution of our own labor shortage will follow along identical lines. The problem is by no means insurmountable.

## PRESENT FUEL SITUATION

Power and materials, the other two factors that make up the balanced ration of industry, are bound up in each other. No matter how great the resources in raw material, these will be of no value unless the power necessary for transportation, manufacturing and fabrication is available. The greatest source of power is through the combustion of fuels. The situation in regard to fuel is so alarming as to call for the most careful consideration. Production of fuel scarcely meets consumption. Regional Director for the U. S. Railway Administration, R. H. Aishton, formerly president of Chicago and Northwestern Railway, states that "There were times last winter when there was not four hours' fuel in the city of Chicago between freezing people to death and keeping them warm." This is not the statement of an alarmist but of a man, who as director of all the great coal-shipping railroads of the Middle West, knows the facts. Concomitant with the greatest demand for coal we have ever experienced we find the greatest natural-gas field of West Virginia failing alarmingly. This brings into the list of coal consumers new users who have formerly depended on natural gas. At the same time fuel oil is steadily becoming harder to obtain and almost prohibitive in cost. The oil-fired forge furnaces of the East and the copper reverberatories and cement kilns of western Texas, Arizona and Utah, the potash producers of Nebraska and the apartment houses of Seattle, alarmed at the fuel-oil situation must and are seeking coal as their salvation. This means another new demand for coal, a further burden on railroad transportation. As the railroad must have more coal to haul more coal the seriousness of the situation increases geometrically.

\*Paper delivered before the Western New York Section of the American Chemical Society, May 31st, 1915

For this situation with all the elements of danger it presents there are three possible solutions:

1. Stimulation of the production and transportation of fuel,
2. Developing efficient methods for utilizing low-grade fuels hitherto practically unused, and
3. Burning fuel so much more efficiently than we now do that the amount available will be adequate for all needs.

An estimate of the possibility of speeding up coal production and coal transportation can be left to those who are at present arguing the pros and cons of whether it is the railroad or the mine which limits production. At best there does not seem to be much reason to expect any great increase in production.

Our greatest opportunity for success in meeting the fuel situation lies in the efficient combustion of both low-grade and high-grade fuels. It is far wiser to save avoidable losses than to increase supply and thus compensate for losses. It is preëminently the patriotic and professional duty of the chemist and engineer to work for the more efficient utilization of fuel. We should therefore study critically the lines along which we should work. Among the more efficient types of combustion is the use of powdered fuel. By considering the nature of powdered coal as a fuel and its combustion characteristics we can learn its possibilities in the present fuel situation. The requirements necessary in perfect combustion show the weaknesses of present methods and the possibilities of powdered coal combustion.

What are the known avoidable losses in combustion? What are the essentials necessary for combustion efficiency?

## ESSENTIALS OF GOOD COMBUSTION

Assuming correct furnace and flue design, and proper and controlled draft, the essentials of good combustion are:

1. *Complete oxidation of all the combustible in the coal to avoid loss of combustible in ash and up the stack.* The loss of unburned carbon in the ash will vary with different types of fuel, different types of ash and the percentage of ash in the coal. It will also vary with the type of stoker used and boiler load carried. In hand-fired practice it will vary with the skill of the fireman; and in producer operation it will vary according to the quality of the coal, type of producer and operating conditions.

Using an Illinois coal of the following analysis:

|                       | Per cent |
|-----------------------|----------|
| Sulphur .....         | 5.5      |
| Volatile matter ..... | 34.0     |
| Fixed carbon .....    | 42.0     |
| Ash .....             | 18.5     |

the results of one of the large users in the Middle West show the following losses in the ash:

| Actual per cent of coal lost                               |                |
|------------------------------------------------------------|----------------|
| Over-feed stokers—25 per cent unburned carbon in the ash   | 4.6            |
| Chain grate stokers—35 per cent unburned carbon in the ash | 6.5            |
| Hand fired—35 per cent upwards unburned carbon in the ash  | 6.5 and upward |

This particular consumer has two different types of stokers and also does a large amount of hand-firing. His consumption is over 100 carloads of coal per day; operation is under the direction of skilled technical men who have actual data as to losses.

In producer operation using a good-grade coal, 20 per cent of unburned carbon in the ash is the minimum figure. Under bad conditions when poor, fine, wet coal was used and with variable steam pressure, as high as 55 per cent unburned carbon will be found in the ash even with a first-class modern producer.

With any type of stoker or producer the loss due to unburned carbon in the ash increases with the increasing ash content. This is not a straight-line function, partly due to the human element, while the increase in unburned carbon with increasing ash is affected considerably by the nature of the ash, its fusibility, etc. Certain coals, although of high heating value, offer enormous difficulties to efficient operation when put through a producer, burned on grates or on stokers. A case in point is a coal obtained in southwestern Virginia not far from Bristol, Tenn. This coal runs over 14,000 B.t.u. and contains under 8 per cent ash. Occurring in this coal are fine laminations of pure crystalline transparent calcite which is present in just sufficient amount to flux the other ash materials and given continuous trouble from clinkering. Even in a modern mechanical producer this coal is a source of continuous trouble and interruption of operation. Due to the mechanical occurrence of the ash washing does no good.

Another case is a Colorado coal of the following analysis:

|                 | Per cent |
|-----------------|----------|
| Ash             | 6.66     |
| Volatile matter | 43.76    |
| Fixed carbon    | 49.58    |
| Sulphur         | 0.93     |
| B.t.u.          | 12886    |

The ash of the coal melts, runs down on the grates and freezes there while the coal itself disintegrates and chokes up the fire.

There is, of course, also the loss of unburned carbon up the stack which although as much as one or two per cent under some conditions should be small with good operation.

2. *Control of combustible and air.* This is absolutely essential, if we are to secure maximum flame temperature with a corresponding increased rapidity of heat transfer. The more rapid the heat transfer in the furnace or boiler the higher the capacity of the furnace and, in general, the greater the efficiency. This may well be shown by the following example: The theoretical flame temperature for hydrogen is 2010 deg. C.; while with 25 per cent excess air, this figure drops to 1764 deg. C. This fact has long been realized in boiler practice and considerable emphasis has been placed on high content of CO<sub>2</sub> in the flue gases and a minimum amount of excess air.

3. *Control of flame length.* In order to maintain in a furnace the conditions which the design of the fur-

nace, the operation, or the metallurgical process occurring therein, requires, it is essential that the length of the flame be under control. An example is found in a recent development in firing copper reverberatory furnaces. For a long time it has been a practice to fire copper reverberatories with an insufficient amount of air, admitting the amount of air required to complete combustion at ports along the side of the reverberatory. It has recently been found with oil-fired reverberatories that if the number of oil burners firing into the furnace is increased and the mixture of oil and air so adjusted as to give complete combustion with a short, hot flame, the capacity of the furnace is increased in some cases as much as 50 per cent, while the fuel ratio is better than anything yet obtained with oil in reverberatory practice. This is also true of powdered-coal-fired reverberatories. In this particular operation it has been found that a short, hot flame leads to most efficient operation and highest furnace capacity; but there are other processes in which the reverse is true.

#### ECONOMIES EFFECTED BY POWDERED COAL THROUGH FURNACE EFFICIENCY

In changing types of fuel, for example in changing from the hand-firing of coal to powdered-coal combustion, the economies met with are usually far greater than those which can be figured from the known losses. The increase in capacity is usually so great that it can only be attributed to increased furnace efficiency. This increased furnace efficiency in all probability follows from the fact that the operator is now able to maintain the flame length and type of combustion for which that particular furnace design is best suited. When, in changing from hand-fired practice to powdered-coal combustion, it is found that only from 30 to 40 per cent as much coal is used as formerly, the greater proportion of the saving is very evidently due to change in the efficiency of the furnace.

4. *That type of combustion which is to be most efficient must possess flexibility in capacity.* Flexibility in combustion means rapid response. Only in this way can a cold furnace be brought to heat very quickly or a standby boiler come up to peak load rapidly. This makes for efficiency because it reduces the fuel consumption during the standby period. Many operations also require considerable variation in heat input at different stages of the operation; in order to secure highest efficiency under these conditions, extreme flexibility as to "combustion load" is demanded.

5. *Control of the nature of the combustion.* In many operations it is not only necessary to heat uniformly, quickly and efficiently, but it is equally important to maintain a certain chemical condition in the furnace. This condition may be oxidizing, reducing or neutral. In any case the control of combustion should be such that the desired condition may be maintained within very close limits; failure to do so means a waste of fuel. Maintaining an oxidizing condition without ability to control it within close limits, will result in having present too much of an excess of air, which will lower flame temperature, lessen output, lower furnace efficiency and reduce fuel efficiency. Likewise a reducing condition, unless maintained within close limits, means that fuel is needlessly wasted. If the operation demands a neutral condition, there may be some loss

due to spoiling of product, unless there is the ability to maintain the neutral condition quite exactly.

#### ONE-STAGE VERSUS TWO-STAGE COMBUSTION

6. *One-stage combustion.* The best example of two-stage combustion is the producer. The producer affords, in many of its applications, an overall efficiency which is considerably higher than that obtained by other methods. Nevertheless we should clearly realize that in the process for making producer gas there is an inherent loss of at least 20 per cent because of the inability to gassify without forming a certain percentage of  $\text{CO}_2$ , due to heat losses at the producer and losses in sensible heat from the gas between the producer and the point at which it is used.

There is another serious objection to two-stage combustion. When combustion is completed, the final flame temperature is lower than in a one-stage process. Unless we resort to such devices as the recuperator or regenerator, high temperatures cannot be reached. Furthermore a two-stage combustion results in "cracking" some of the most valuable constituents of the coal with the formation of smoke in the furnace and soot in the producer. This has been shown very well by Kreisinger, Augustine and Ovitz in *Bulletin* 135 of the Bureau of Mines, in their study of the combustion of coal and furnace design.

Having considered the essentials for efficient combustion, we can correctly estimate the value of powdered coal as an efficient fuel, by studying its characteristics, and seeing to what extent these make it possible to maintain the essentials of good combustion. In the same way we can also ascertain the conditions demanded for success in the combustion of pulverized fuel.

#### FUEL CHARACTERISTICS OF POWDERED COAL

The simplest way to regard the combustion of coal is that it is a reaction between solid fuel and oxygen. It is therefore a heterogeneous system; consequently the velocity of the reaction and its completeness will depend upon the surface exposed by the solid, the pressure of the reacting gas and the intimacy of the mixture. By grinding an inch cube of coal so fine that 85 per cent will pass a 200-mesh screen, we have increased the surface exposure from 6 square inches to approximately 1800 square inches. We have therefore increased the velocity of combustion approximately 300-fold. By doing so, we have immediately changed the characteristics of the fuel. We now have a fuel relatively 300 times more active than the inch cube of coal, a new type of fuel which has in it inherent possibilities not met in lump or slack fuel. By increasing the surface exposure 300-fold, we have speeded up combustion proportionately. This carries with it a further effect. The increase in combustion velocity also increases the rapidity of heat evolution, and consequently quickly raises the temperature of the rest of the material. This temperature rise, which is much more rapid than in the normal combustion of coal, will double the velocity of combustion each rise of 10 deg. C. The increased velocity due to greater surface exposure and that due to temperature rise are superimposed on each other so that we have with pulverized fuel a combustion which is hundreds of times faster than when burning lump coal.

Having a finely divided fuel it is possible to form a mixture of fuel and air so intimate that each small particle of coal is surrounded by the proper amount of air. In this condition, by maintaining the proper velocity of the air current, the fuel can be carried into the furnace in suspension and there burned completely, efficiently and rapidly.

#### ESSENTIALS FOR COMBUSTION EFFICIENCY

It is of course a simple matter to mechanically control the amount of powdered coal delivered to the furnace in a given time. It is also quite possible to control the amount of air delivered with the coal. If, then, we deliver to the furnace an intimate mixture of air and powdered coal and have control of the amount of coal dust and air delivered, we have the prime essentials for highest combustion efficiency. These are the possibilities in utilizing coal in powdered form. The degree to which they are attained depends entirely upon how carefully we study the characteristics of the fuel before and during combustion.

The amount of coal dust delivered to the furnace can be controlled simply and positively by using as a feeder a properly designed screw, operated at variable speeds. It is also a simple matter to control the volume of air admitted with the fuel. But the highest efficiency possible with this type of fuel will not be obtained unless we work out a correct way in which to mix a finely divided solid with air.

A study of the methods for making such a mixture, immediately shows that the methods commonly used in making uniform mixture of two miscible liquids or a uniform solution of a solid in a liquid, or the methods used in mixing finely ground solids are not only useless in this case, but will actually separate the coal dust from the air. Ordinary mixing is done by agitation; this agitation is usually accomplished by baffling, stirring, shaking or similar devices. When, however, such methods are applied to a mixture of gas and finely divided solid, the solid tends to separate out due to its much higher specific gravity. This, in fact, is the principle of the well-known Cyclone dust collector. Any mixing device which results in such agitation of the dust and air as to give a centrifugal effect, will tend to separate out instead of mixing the air and the dust. Any mixing device along these lines must necessarily fail to give an intimate, perfect mixture.

The importance of intimately mixing the coal dust and air cannot be exaggerated. The rapidity of combustion is a direct measure of the intimacy of mixture. This is well illustrated by comparing the ordinary gas flame with the flame obtained in the Bone combustion system. The Bone system consists in forcing the proper proportions of air and gas through a diaphragm having numerous small interstices which results in a mixture that is nearly perfect. When this mixture is ignited on the other side of the diaphragm, we have only a film of flame.

#### IMPORTANCE OF THOROUGH MIXING

The poorer the mixing the longer the flame. The flame simply outlines the area in which combustion is taking place and the length of the flame is a measure of the time element necessary to accomplish combustion. This time element—other conditions being equal—is

absolutely a function of the intimacy of mixture. This has already been noted by Breckenridge some ten years ago, when in *Bulletin* No. 325 of the United States Geological Survey, page 171, he stated:

"The conclusion is reached that the velocity of combustion decreases enormously from the surface of the fire to the rear of the combustion chamber, where it is relatively very small, the practical application is that little is to be gained by adding further length of smooth combustion chamber, which would be commercially as poor an investment of capital as to add to the length of a Corliss engine cylinder and stroke; we must resort to thorough mixing."

On page 178 of the same bulletin, Breckenridge further stated:

"Mere length of combustion chamber counts for little—that mixing is what counts."

These two excerpts from Breckenridge's study of four hundred steaming tests have since been amply confirmed by the work of Kreisinger, Augustine and Ovitz, in *Bulletin* No. 135 of the Bureau of Mines. The work of these investigators confirmed and emphasized the previous observations of Breckenridge and they quote him as I have. They also state on page 130:

"Evidently, the length of the flame depends not only on the nature of the combustible, the excess of air, and the rate of firing but also to a large degree on the rate of mixing of the combustible gases with the oxygen of the air. It has been shown that the tendency of the gases is to flow in parallel streams even when the air was introduced into the furnace in many small streams through the tuyeres of the furnace."

So far we have considered this type of fuel from the point of view of the possibilities which it affords. We have also studied the characteristics of the mixture of coal dust and air in order to ascertain what methods should be employed to insure delivery to the furnace of an intimate, controlled mixture of fuel with the requisite amount of air. A fuel having the great possibilities offered by a finely divided combustible, is of extreme importance especially under present conditions. Because of these possibilities, all of which are capable of being realized and which are satisfied by commercial equipment now on the market, there is less excuse for permitting inefficient operation with this fuel than with stoker or hand-fired practice. Apparatus, properly designed and fundamentally correct in principle, will give proper efficiency. Such apparatus by giving an intimate and controlled mixture of fuel and air to the furnace will permit the highest furnace efficiency.

#### CHARACTERISTICS OF POWDERED COAL AND FUEL OIL

Just as in the past there has been a remarkable failure to realize the necessity for intimately mixing air and coal dust, neither has there been sufficient consideration of the characteristics of this fuel when burning. Powdered coal has the characteristics of a rich fuel of somewhat higher kindling temperature than producer gas, natural gas or fuel oil. To illustrate the fact that it is a rich fuel, we can compare the available B.t.u. in a cubic foot of a correctly proportioned mixture of powdered coal and air and the available B.t.u. in a cubic foot of a correctly proportioned mixture of pure methane and air. Taking a Pittsburgh vein coal (heating value 14,157 B.t.u.) of the following analysis:

|                    | Per cent |
|--------------------|----------|
| Volatile .....     | 35.4     |
| Fixed Carbon ..... | 58.5     |
| Ash .....          | 6.1      |

we find that a cubic foot of a correctly proportioned mixture of coal dust and air has available 107 B.t.u., while a mixture of pure methane and the proper amount of air has available per cubic foot, 62.3 B.t.u.

A further illustration is shown by the theoretical maximum flame temperatures of several fuels.

#### THEORETICAL MAXIMUM FLAME TEMPERATURE USING COLD AIR

|                                              | Deg. C. |
|----------------------------------------------|---------|
| Hydrogen .....                               | 2010    |
| Carbon Monoxide .....                        | 2050    |
| Natural Gas .....                            | 1906    |
| Pure Methane .....                           | 1958    |
| Pittsburgh Coal (Analysis given above) ..... | 3470    |

#### FACTORS CONTROLLING RAPIDITY AND COMPLETENESS OF COMBUSTION

The rapidity of combustion and the completeness of combustion of a mixture of coal dust and air depends upon a number of factors:

1. *The velocity and pressure at which it is passed into the combustion chamber.* If the velocity of the incoming stream of powdered coal and air is above the velocity of flame propagation, combustion will not take place until the mixture has slowed down to a point where it does not exceed the velocity of flame propagation. When powdered coal is fired at high pressure and high velocity, combustion frequently does not begin until a point four to six feet from the mouth of the burner. A similar example is found in the plumber's blow-torch when too much air is used, or in the Bunsen burner when the gas pressure is too high. High-pressure, high-velocity firing not only slows down combustion thus increasing the size of combustion chamber necessary, but has a destructive action on the furnace. It has been well established that high velocities in the combustion chamber or a blow-torch effect due to firing at high pressure (whether oil or gas be used as a fuel) are always very destructive to the brick work. This action is increased in high-pressure firing of powdered coal since in addition to the erosional effect of gases at high temperature traveling at high velocity, there is a fluxing action by the melted ash. Furthermore, with such high-velocity combustion, the slagged ash will be carried along mechanically, leading to further furnace troubles. In one case this resulted in a serious deposit of slag on the mud drum of a vertical waste-heat boiler at the end of a long reverberatory furnace. Slowing down the velocity not only hastens combustion, but makes it possible to eliminate much of the slag. When the velocity is low the coalesced particles of slagged ash are either larger than will be carried by the velocity of the gas or this condition is so nearly approached that a slight change in direction of the flame will result in dropping out the slag. Thus, in addition to being correct combustion and necessary in order to avoid excessive furnace maintenance costs, low-pressure, low-velocity combustion permits by slight change in flame direction dropping out a very large percentage of the slagged ash in the early part of combustion, where it can be removed and will not interfere seriously with efficient metallurgical operations.

The velocity of combustion is not only dependent upon the fineness of the particles of coal, intimacy of mixture and the velocity of the stream of combustible and air, but is affected by the temperature of the combustion chamber. The kindling temperature of a mixture of powdered coal and air is

higher than either that of oil or gas; consequently for successful and complete combustion, it is necessary that the combustion chamber be maintained above a certain minimum temperature and that combustion is practically complete before the products of combustion pass over the heat absorbing surfaces. Just as you can extinguish a gas flame by passing over it a piece of wire gauze, so the effect of a chilling surface will be even more marked with this combustible material than burning gas, since the particle of coal is infinitely larger than a molecule of gas and the kindling temperature is also higher. This has a direct application in the successful firing of locomotive-type boilers, water-tube boilers and return-tubular boilers. If the combustion of powdered coal is not sufficiently developed before the flame enters the tubes of the locomotive-type boiler, combustion will be checked and coked coal settle out in the tubes. If on the other hand combustion is sufficiently developed before the flame is brought in contact with the heat-absorbing surface, a complete combustion and high efficiency are obtained. In any furnace operation and in furnace design, this must be borne in mind if success is to be expected.

#### RAPIDITY OF COMBUSTION OF LOW-PRESSURE MIXTURE

A study of the flame developed by a low-pressure, intimate mixture of coal dust and air shows that combustion is extremely rapid. In a copper reverberatory furnace in Florence, Colorado, where this type of combustion is used, coal burned at the rate of approximately one ton per hour develops a flame which vanishes within six feet of the burner, combustion being complete at that point. In order to bring out exactly what this means, let us translate it into terms of natural gas, in which case the fuel consumption would be approximately 26,000 cubic feet per hour or 433 cubic feet per minute. Picture to yourself this quantity of gas being burned at low pressure and developing a flame only six feet long. Gas samples taken in the flame, show a content of CO<sub>2</sub> as high as 16 per cent only five feet from the mouth of the burner. This will give an example of the rapidity with which combustion can be obtained and the extremes which are possible in shortening the flame. It is equally possible with proper equipment to lengthen the flame until it will spindle out a distance as great as 100 or 120 feet. However, with an intimate controlled mixture, this must be done by supplying insufficient air. Under such conditions combustion is incomplete and the flame spindles out because combustion continues to develop throughout the length of the furnace as air leakage supplies additional oxygen. This is an additional proof of the statement previously made that the length of flame is an actual measure of efficiency of mixing and the adjustment of the fuel-air ratio.

Thus it is seen that we have changed entirely the characteristics of coal as commonly known. Powdered coal is a fuel of extreme flexibility in that the amount burned can be varied within wide limits. It is a fuel which develops a flame the length of which can be adjusted. The character of the flame can be altered to suit the metallurgical operation. In short the basic fuel, coal, has acquired the characteristics of oil or gas, but with better and closer control than in the case of oil or gas. Furthermore, the possibilities of this

fuel are not only capable of realization, but are actually being utilized in commercial practice today. To the flame characteristics of a rich fuel, developing a flame like oil or gas, is added a degree of control not yet obtainable in burning either oil or gas. This statement is made advisedly. The possibilities of such combustion for the improvement of processes, for fuel economy, for increasing output, through its ease of control and elimination of heavy labor, are today realized by few. Due to the psychological attitude of labor and the scarcity of skilled operatives, it is far more difficult than ever before to secure high efficiency and good operation in hand-firing, stoker-firing or in producers—in short wherever such efficiency depends upon constant watchfulness and hot, heavy, disagreeable work. For these conditions powdered coal substitutes an ease of control such that the equipment can be handled by an old man or a boy, while it is so simple that a man of ordinary intelligence can soon be taught all that is necessary for good efficiency in operation. The possibilities of such control in the place of present day combustion methods, which permit high efficiency only by the most strenuous effort, through substituting for these a type of combustion whereby high efficiency is easily obtained, is certainly of great importance to us at the present time.

#### CONTROL OF HEATING CONDITIONS IN CHEMICAL PROCESSES

To those who are in touch with many diversified chemical industries, the possibility of maintaining within close limits, heating conditions which are oxidizing, reducing or neutral at will, conditions which once adjusted will remain constant—barring mechanical or electrical interruptions—will undoubtedly suggest many cases where such combustion will offer new economies and betterments in their processes. A good example of this is shown in a powdered-coal installation in a malleable iron foundry in Buffalo. The positive and simple control offered by their equipment has not only resulted in the highest fuel ratio yet reached in malleable-iron practice, namely between 5 and 6 lb. of castings per pound of coal, but also through maintaining a slightly reducing condition in the annealing oven the oxidation of the cast-iron pots has been so reduced that the cost of pots per ton of castings has been cut from \$2.25 to 83 cents. These two results are concrete proof of the possibilities of this type of combustion. The high fuel-ratio shows efficient combustion; the decrease in pot cost shows control of combustion; and the high fuel-ratio in conjunction with the maintenance of a reducing condition shows exactness of control.

A still more striking example of the possibilities of controlled combustion may be cited of a powdered-coal installation now being made. In this particular process a cast-iron container is maintained continuously at a temperature of 1000 deg. C. This is not only close to the melting point of the material but is a temperature so high that the oxidation caused by the unavoidable excess of air met in ordinary methods of combustion results in enormous maintenance costs due to quick failure of the container. In this installation it is confidently believed that the combustion can be so controlled as to cut oxidation to a minimum so that the life of the container will be greatly increased.

#### EFFECTS OF ADMINISTRATION EFFORTS AT FUEL DISTRIBUTION

The Fuel Administration has wisely districted the coal fields of this country. In doing so they have upset in many cases what has been standard practice for years in some of the industries. The cities of Iowa have for years used anthracite for house heating; today they must use Iowa and Illinois coal. The malleable-iron foundries of Chicago have in the past bought Elkhorn coal from Kentucky with which to melt iron in the air furnace; today they are confronted with the problem of using high-sulphur, low-grade, Middle Western fuel. While temporary relief will undoubtedly be granted through permits to use high-grade coal for melting, it is probably only a question of time before they will be compelled to work out successful methods for burning the lower-grade coals of their immediate vicinity, from which they should naturally draw their supply of fuel. Nebraska must learn to use her lignites, as must the Dakotas. Western Texas must do the same. Seattle, which has in the past heated apartment houses with fuel oil, must learn to do so with the lignitic coals of Washington.

While these communities are facing the problem involved by the use of these low-grade fuels, every user is experiencing a marked decrease in the quality of his coal, regardless of the source. In the J. E. Aldred lecture delivered at Johns Hopkins University this year by Mr. E. G. Bailey, he shows that due to the enormous demand for fuel, shortage of labor and other conditions, the ash content in coal has increased during the year of 1917 at least 5 per cent, resulting in an increase in coal consumption, due to the decreased heating value and lower efficiency, which reaches as high as 10 per cent. Figuring on a basis of six hundred million tons of coal produced and marketed last year, thirty million tons of dirt, slate and rock were handled in excess of what the coal would normally contain. At a price of \$2.50 f.o.b. mine and a freight rate of \$1.50 per ton, the consumer has paid \$120,000,000 for worthless material. The additional cost of firing this coal, repairing furnaces, stoker and locomotives and the cost of handling the ashes, will add some millions of dollars more.

The coal consumer today is obtaining not only a poorer grade coal than formerly but a coal much more difficult to burn efficiently, due to increased content of sulphur balls, slate and bone. Not only is this true, but a big variation in the quality of coal leads to further inefficiencies. Stoker practice and our present settings are largely designed for a particular type of coal of a certain grade. The flexibility of such equipment in handling efficiently considerable variations in quality of fuel and nature of ash is limited. Under such conditions powdered coal by reason of its characteristics as a fuel offers us in many cases a solution of the problem.

#### BURNING LOW-GRADE FUELS IN SUSPENSION

In burning low-grade fuels in suspension the only loss in efficiency is that due to lower flame temperature caused by the increasing amount of ash and the heat lost in the ash. Coals running as high as 30 to 40 per cent ash can be successfully burned; combustion will be complete and maximum flame temperature for that fuel will be obtained. The only difference between burning a fuel of

this type and a high-grade fuel is the difference in flame temperature and the heat loss in the slagged ash. An ash whose slagging character would lead to enormous difficulties in producer or stoker operation will simply melt the easier when the coal is burned in powdered form and can therefore be dropped out earlier in the furnace, which in many cases constitutes an actual advantage. The lignite fuels of the Middle West and the Far West can be burned successfully and are being burned successfully in powdered form. An enormous field is opened up through ability to burn with efficiency these lower-grade fuels. It will eliminate long hauls of fuel by our railroads, release motive power and cars, and conserve our fuel reserves.

An unusually good illustration is found in two coals previously mentioned, one a Virginia coal more than 14,000 B.t.u. and less than 6 per cent ash, and the other a Colorado coal. Both of these are practically unavailable as fuels when using stokers, grates or producers, because of the chemical nature of the ash and its mechanical form. When, however, these coals are pulverized, the distribution of the ash in the lump coal has no effect, while the low melting-point of the ash in many cases offers a decided advantage. These coals both afford splendid fuels of high heating value when burned in powdered form. The Colorado fuel is being burned successfully this way. The River Smelting and Refining Company which is burning this Colorado fuel has cut the fuel requirements per ton of ore smelted in a reverberatory to  $\frac{1}{2}$  that necessary when this coal was burned on grates.

It has been the object of this paper to discuss the unusual characteristics of powdered coal as a fuel; not only the characteristics of the fuel before being burned, which of necessity dictate the principles which must be made use of in designing proper equipment and which give us an idea of the possibilities offered by this fuel, but its more striking possibilities have been shown. Many of these are actually being obtained commercially today. From your knowledge of your own industries, no doubt many other possibilities will suggest themselves to you.

Chicago, Ill.

**Gasoline Recovery from Natural Gas.**—Gasoline recovery from natural gas by compression and refrigeration has been systematically treated in *Bulletin* 151, Bureau of Mines, by W. P. DYKEMA. Conditions of actual operation and the equipment in use are described. The vapor pressure of gasoline being relatively low compared to that of marsh gas, etc., it has been found that the percentage content of gasoline decreases greatly with high pressure, so that the most favorable sources of supply are low pressure gas wells. Up to five or six years ago, coils were used by most operators in compressing 200,000 to 300,000 cubic feet daily. The gas used yielded from four to six gallons of gasoline per 1000 cu.ft. of gas. At present, plants are in operation having multiple compression with elaborate cooling effects, in which as much as 9,000,000 cu.ft. of low-grade gas is used having only one gallon of gasoline per thousand cubic feet. From 100 to 300 barrels of water are required for cooling 1,000,000 cu.ft. of gas at 250 lb. per square in. working pressure per day.

## Chemical and Metallurgical Notes from Japan

BY KATSU YASUI

### POTASSIUM CHLORATE

Prior to the present war, there was only one factory manufacturing potassium chlorate in Japan, with an electric power consumption of 2850 kw. hr. According to late government reports, the number had increased to seventy factories in August, 1917, with a power consumption of 14,000 kw. hr.

### MATCHES

Instead of being one of the chief imports to the Orient, matches have now become one of the principal exports (of Japan), a trade being even established in America. The statistics for last year are:

|                   | Cartons     | 12 Boxes | Value      |
|-------------------|-------------|----------|------------|
| Common match      | 445,112,000 |          | 11,662,000 |
| Yellow phosphorus | 146,372,000 |          | 1,974,500  |
| Specialties       | 15,870,000  |          | 267,500    |
| Total             | 607,321,000 |          | 13,904,000 |
|                   |             | Cases    |            |
| Exports           | 41,321,000  |          | 10,551,500 |

The price of matches has advanced with the general rise in raw materials. The average price per carton and the total value of the yearly production have been compiled as follows:

|      | Per Carton | Value of Production |
|------|------------|---------------------|
| 1912 | \$0.13     | \$7,073,000         |
| 1914 | .16        | 7,722,000           |
| 1915 | .23        | 11,385,000          |
| 1917 | .27        | 13,904,000          |

### NITROGEN

The government has made a large appropriation of money to help create a domestic nitrogen industry, in recognition of the indispensability of nitrogen products for agriculture, industry and ordnance. The statistics for local production in tons are:

|                          | 1913  | 1914   |
|--------------------------|-------|--------|
| Ammonium sulphate (tons) | 7,400 | 15,900 |
| Calcium cyanamide (tons) | 2,500 | 5,000  |

The imports in 1913 were:

|                   | Tons    | Value       |
|-------------------|---------|-------------|
| Ammonium sulphate | 110,000 | \$8,000,000 |
| Sodium nitrate    | 26,500  | 1,450,000   |

About 60 per cent of the sodium nitrate was used in industrial and explosive works, the remainder, for agriculture. During the war, the demand has been three-fold times as great and the supply very inadequate.

### TIN PLATE AND CANS

The Nitto Steel Manufacturing Co. of Kawasaki, near Tokyo, has increased its capital to \$2,500,000, and has started the construction of a tin-plate department with a capacity of 15,000 tons per annum. The Oriental Can Manufacturing Co. has placed orders in the United States for can-making machinery and is waiting for delivery which is very slow because of the present scarcity of ships.

### HIGH-SPEED STEEL

The Japan High-Speed Steel Works, near Tokyo, which was founded by Mr. Totaro Ezaki, is being greatly enlarged and will have 40 rolling mills and steam hammers. Capital \$1,500,000.

### CYANIDE AND MERCURY IMPORTS

|                    | 1915      | 1916      | 1917      |
|--------------------|-----------|-----------|-----------|
| Potassium Cyanide: |           |           |           |
| Quantity (tons)    | 330       | 513       | 246       |
| Value              | \$181,896 | \$324,578 | \$195,337 |
| Sodium Cyanide:    |           |           |           |
| Quantity (tons)    | 175       | 270       | 270       |
| Value              | \$82,175  | \$138,348 | \$161,970 |
| Mercury:           |           |           |           |
| Quantity           | 137       | 284       | 200       |
| Value              | \$216,693 | \$639,674 | \$464,691 |

### ORES MINED

|           |                 |
|-----------|-----------------|
| Gold      | 1,554 oz.       |
| Silver    | 41,800 oz.      |
| Copper    | 8,400 tons      |
| Iron      | 7,573 tons      |
| Coal      | 1,815,637 tons  |
| Sulphur   | 5,242 tons      |
| Petroleum | 160,000 barrels |

### CHEMICAL MANUFACTURING CENSUS

| Industry            | No. of Factories | Employees |
|---------------------|------------------|-----------|
| Ceramic             | 962              | 49,293    |
| Paper               | 277              | 21,309    |
| Lacquer             | 5                | 192       |
| Leather             | 48               | 3,968     |
| Powder              | 255              | 31,177    |
| Oil and wax         | 74               | 4,619     |
| Pharmaceutical      | 183              | 9,281     |
| Rubber              | 99               | 8,178     |
| Toilet goods        | 21               | 1,021     |
| Color, paint, paste | 69               | 2,695     |
| Fertilizer          | 58               | 6,277     |
| Miscellaneous       | 63               | 4,049     |
| Total               | 2,146            | 143,631   |

### MOLYBDENUM

Molybdenum ores have been found at Gifu Prefecture, Onari-gun; Toyania Prefecture, Shinkawa-gun; Niigata Prefecture, Kambara-gun; Totori Prefecture, Nogi-gun and Ohara-gun; and Hyogo Prefecture, Shishikuri-gun. While only 5.6 tons were mined in 1914 and 11.1 tons, in 1915, the output is expected to increase greatly, making Japan one of the prime producers of molybdenum.

### Trained Men Wanted by Bureau of Mines

Important chemical and other technical engineering work necessary for the prosecution of this war is being carried on by the Bureau of Mines Experiment Station, at Washington, D. C. The services of trained men of the following classifications are urgently needed:

|                                      |                                |
|--------------------------------------|--------------------------------|
| Bacteriologists                      | Instrument Makers              |
| Biologists                           | Laboratory Assistants          |
| Chemists, Inorganic                  | Laborers                       |
| Chemists, Organic                    | Machinists                     |
| Chemists, Physical                   | Physiologists                  |
| Chemists, Electro-chemical Engineers | Plumbers                       |
| Draftsmen                            | Steamfitters                   |
| Electrical Engineers                 | Stenographers                  |
|                                      | Skilled labor of various kinds |

If your training fits you for any of these occupations, send to the

Bureau of Mines,  
American University Experiment Station,  
Washington, D. C.

for blank forms. When properly executed and returned by you, these forms will be placed on file, and when a vacancy occurs you will be considered for it and will be notified if your services are desired.

If you are a registrant in the draft, and have not yet been ordered to camp, it may be possible to have you immediately inducted into the service for work here. If you are not in the draft, but feel that you wish to serve your country in the present crisis, you can enlist, or serve as a civilian.

## Synopsis of Recent Metallurgical and Chemical Literature

**Occluded Gases in Ferrous Alloys.**—The February, March and April *Journal* of the Franklin Institute contains an important contribution on the above subject by GELLERT ALLEMAN and C. J. DARLINGTON of Swarthmore College. The first part of the paper contains an extensive review of the literature, showing the extremely various results and views attained by individual investigators. Troost and Heutefeuille in 1873 concluded that gas bubbles formed on solidifying metal were forced out of solution on cooling. Parry in 1881 found that his former results were somewhat in error owing to the fact that the iron carbide in the metal reacted with the silica of the container, giving carbon monoxide gas and a high silicon alloy. This fact was controverted by Baker (1909) but re-established by the present authors. Parry's results were received with much skepticism on account of the large volumes of gas obtained—up to 340 volumes. Poursel in 1882 investigated the effect of various ferro-alloys in reducing the number of blowholes in steel ingots, and concluded that aluminum or silicon steel contained no gas if no manganese were present, but 2 per cent manganese occluded large quantities of hydrogen. Henry M. Howe (1892) wrote that the gases nitrogen, hydrogen and carbon monoxide dissolve in molten iron and their escape is what causes blowholes. Braune (1903-1906) concluded, however, that nitrogen was present as nitride, probably  $\text{Fe}_3\text{N}_2$ , and its presence could be detected microscopically by observing the increase in crystalline structure of the ferrite grains, closely resembling uniform pearlite on high nitrogen contents. von Malitz (1907) concluded that heating melts to a very high temperature diminishes the tendency of iron to absorb hot gases, but Sieverts (1910) found the opposite. Boudouard (1907) found that evolution of gases commenced in all cases at a red heat, while repeated heatings did not entirely remove the gas. He also records that volatilization of the iron commences at 900 deg. C. and is very noticeable at 1100 deg. C. Baker (1909) concluded that mechanical work diminished the volumes of the evolved gas some 50 per cent. He failed to find the appreciable dissociation pressure to be expected if the gas were due to the decomposition of ferrous compounds, and therefore thought that the gas was imprisoned as such in the pores of the steel, to be driven out on heating in vacuo. On the other hand Heroult (1910) and Goerens (1910) say that cold steel of any manufacture does not contain any appreciable amount of gases, blowholes being formed largely by carbon monoxide produced by reaction between carbides and oxides. Sieverts (1910) found that nitrogen was absorbed by gamma iron only.

### HYDROGEN OCCLUDED INCIDENTAL TO ELECTROLYTIC ACTION MAKES IRON BRITTLE

Large quantities of hydrogen are occluded by iron incident to electrolytic action, making it very brittle. Roberts-Austin (1899) thinks that a critical point of

481 deg. C. is due to the formation of a hydride, and another at 261 deg. C. of an eutectic. Iron in an acidulated solution absorbs hydrogen at a point lower than the decomposition voltage, using up chemical energy to change the molecular structure of the iron.

The present authors think that these divergencies are largely due to the porosity of the containers at high temperatures, allowing infiltration of air and flame-gases, and also to the fact that the heating was not sufficient. Preliminary experiments indicated that quartz tubes reacted with the metal, rapidly devitrified and became porous. Special alundum tubes, 1 in. diameter and 24 in. long, were consequently wound for 5 in. with 20 ft. of No. 20 molybdenum wire, plastered with alundum cement and wrapped with two layers of asbestos rope. This tube was centered into a welded iron jacket, 8 in. diameter by 10 in. long, entering through 2 in. nipples at each end. The joint at this point is sealed with alundum cement, wound with okonite tape and covered with rubber cement. The whole protruding ends are then covered with a glass bulb, one of which is connected with an air pump. The heating current is led in through the iron casing by two iron bolts cemented into flanged openings by alundum cement and rubber stoppers, on the outside of which were layers of bakelite and rubber cement. It is absolutely necessary that a vacuum as complete as possible be maintained in a perfectly gas-tight container, else the molybdenum wire will burn readily. With this apparatus a temperature of 1800 deg. C. may be gradually attained and maintained for 5 minutes.

### HYDROGEN LARGEST CONSTITUENT OF GAS EVOLVED AT 950 DEG. C.

Experimenting with iron wire at about 950 deg. C. they found hydrogen to be the largest constituent of the gas evolved, no oxygen or carbon monoxide being found. Basic open hearth steel (1.05% C) evolved 198 volumes of gas after 35-hours heating in a quartz tube at from 940 to 1470 deg. C., the gas consisting of 60 per cent carbon monoxide, while another sample more rapidly heated gave a mixture containing 80 per cent  $\text{CO}$ . Bessemer steel (0.08 C) heated 23 hours at 1100 deg. C. evolved 55 volumes of gas consisting largely of hydrogen. The same steel heated in the improved furnace in an alundum boat evolved 220 volumes of gas of the following analysis:

| Gas                  | At 1,000° C. | At 1,250° C. | At 1,500° C. | At 1,675° C. |
|----------------------|--------------|--------------|--------------|--------------|

| Oxygen.....          | 2.4          | 3.07         | 4.28         | 6.25         |
| Carbon monoxide..... | 48.9         | 56.10        | 18.75        | 8.42         |
| Hydrogen.....        | 21.16        | 15.08        | 4.20         | 1.10         |
| Nitrogen.....        | 26.46        | 25.13        | 72.77        | 84.23        |
| Total.....           | 100.00       | 100.00       | 100.00       | 100.00       |

The authors conclude that the gases are mostly evolved from interaction of iron oxides, nitrides, carbides and hydrides, certain of which exercise deleterious effects on the steel, and the removal of which will show marked change in microstructure and increase in density. Hydrogen is most readily freed, carbon monoxide next, and nitrogen is held tenaciously. So-called deoxidizers may act as a catalyst to prevent occlusion of gas at high temperature or promote its elimination at lower.

## Recent Metallurgical and Chemical Patents

**Denitration of Sulphuric Acid.**—INGENUIN HECHENBLEIKNER, of Charlotte, North Carolina, patents the process and apparatus of denitration of sulphuric acid together with the oxidation and hydration of the nitrogen oxides in one operation, recovering thereby a pure nitric acid. As shown in Fig. 1, he introduces nitrified acid from tank 13 through the distributor, whence it trickles through the tower-filling against rising steam introduced through pipe 11. The nitrous

FIG. 1—DENITRATION OF SULPHURIC ACID

gases thus driven out by the steam are oxidized and hydrated to form nitric acid by the oxygen blown in through distributor 18, oxidation being particularly rapid in the presence of ozonized air. As a great amount of steam must be utilized for denitration concentrated sulphuric acid is showered through the distributor head 21 in the upper part of the column for the purpose of removing part of the water contained in the nitric acid fumes. Concentrated sulphuric acid is preferably used because it possesses manifest advantages for drying nitric acid fumes which contain a relatively great amount of surplus steam. Furthermore, the sulphuric acid thus added equalizes the concentration of the denitrated sulphuric acid escaping through the siphon 12, since denitration cannot be completed if the concentration of the sulphuric acid is less than 60%, while for practical purposes the

best denitration can be accomplished by a concentration of between 60 and 70% sulfuric acid. The dry nitric acid vapor is drawn into the condenser, conventionally represented at 22, where the pure material is recovered. (1,264,512; assigned to the Southern Electro-Chemical Co., April 30, 1918.)

**Process and Apparatus for Concentrating Acid.**—INGENUIN HECHENBLEIKNER of Charlotte, North Carolina, patents the apparatus for producing 98 per cent sulphuric acid shown in Fig. 2, together with the process of operation. The weak acid is introduced at the top of the tower 10b, and trickles down through the acid proof filling against a counter current of hot gases. A fan drives air through the bustle pipes 5 and tuyeres 7 into the bath of acid. The air is previously heated to about 400 deg. C. by gas or oil burners at the ends of the fire-brick lined pipes 5. The heated air agitates the bath and absorbs water at a temperature below the boiling point of the acid,

FIG. 2—CONCENTRATION OF SULPHURIC ACID

issuing at the surface of the acid at a temperature of about 200 deg. C. This heat is largely transferred to the descending droplets of weak acid in the checker-work above. In order to catch the last trace of acid in the cooled gases exhausting through pipe 15, a condenser 16, filled with acid-proof material is employed. The weak acid recovered here is drawn off from the air seal bottom, as is also the concentrated acid from the bath 8. By removing the moisture without boiling the acid no substantial loss in acid is experienced, while the method is also claimed to utilize heat very efficiently. (1,264,509; assigned to Southern Electro-Chemical Co., and 1,264,182; April 30, 1918.)

**Separation of Potassium Salts.**—GUY STERLING, of Salt Lake City, Utah, patents a process for recovering a mixture of potassium and sodium salts from the mother liquors of natural brines which usually contain a large amount of magnesium salts. He mixes about 0.8 parts by weight of the mother liquor salts with 0.5 parts of silica, and 0.85 parts of limestone, all finely powdered. He then heats the mixture to about 1400 deg. C. for three hours, stirring the mass, when the potassium chloride, potassium sulphate, and sodium chloride largely sublime, leaving behind a complex calcium-magnesium-sodium-silicate. A magnesium-free concentrate is thus produced. (1,264,572; Apr. 30, 1918.)

**Production of Percarbonates.**—OTTO LIEBKNECHT, of Frankfort-am-Main, Germany, patents the process of precipitating percarbonates from hydrogen peroxide sodium carbonate solution with excess of sodium chloride. (1,263,258, May 21, 1918.)

**Pulverized Fuel Burner.**—T. B. CRAM, of Chicago, Ill., patents the burner illustrated in Fig. 3, whereby a short, hot flame may be had when burning pulverized coal. Air enters through pipe 8, a portion of which passes through nozzle 17, sheathing a jet of pulverized coal entering through pipe 16 with a layer of cold air travelling at a considerably higher velocity. This

FIG. 3—PULVERIZED FUEL BURNER

sheath keeps the metal parts and the upper opening 14 cool and free from flame and at the same time sets up a swirling motion as indicated in the vertical combustion chamber. The fuel ignites and partially burns in this chamber, at the lower part of which it meets at an angle a stream of air coming through pipe 19 containing sufficient oxygen for completing the combustion, which is effected immediately in a short, hot, and smoke-free flame. (1,258,654; Mar. 12, 1918. Assigned to Railway Materials Company.)

**Agglomerating Oxidized Ores.**—A. S. DWIGHT, of New York City, patents a method of utilizing the familiar Dwight-Lloyd roaster for the agglomeration of oxidized material, especially iron ores. He notes that the formation of silicates so desirable when sintering sulphide ores must be avoided in a treatment of oxidized ores preliminary to their being smelted. He therefore feeds a well mixed stream of ore, carbonaceous material and flux on the pallets. The carbonaceous material is ignited and its combustion sufficiently heats and reduces the oxidized ores that the various basic oxides form compounds below the temperature of silicate formation. The ore mixture is spread in a thin layer so that the heated gases readily escape without the formation of hot pockets where silicates might be formed. A sufficient excess of carbon is placed in the original mixture so that at the end of the process enough will remain to complete the reduction to metallic state on further smelting. (1-254,316; Jan. 22, 1918.)

**Chromium Compounds of Azo Dyes.**—RENE BOHN and PAUL NAWIASKY of Germany have found that chromable azo coloring matters containing at least one hydroxyl and one sulphuric acid group can be made to yield soluble chromium compounds by being heated with a chromium salt in the presence of water. It is equivalent whether the free sulfonic acid or hydroxyl groups or a salt of such groups be present. The azo coloring matters which are derived from ortho-amino-phenols or ortho-ammino-naphthols or anthranilic acid or benzidine disulphuric acid or toluidine disulphonic acid or from a derivative of any one of these compounds are useful for this purpose whereby in particular salicylic acid and derivatives thereof may be employed as the other component. The new compounds are soluble in water and have an intense color and can be applied for printing purposes, the compounds thus obtained being better and more completely fixed and consequently faster than the prints obtained by applying the chromable azo coloring matter in the presence of a chromium salt to the fiber. The new compounds, after being printed on the fiber, can be fixed by means of alkaline reagents, such for instance as sodium carbonate, or ammonia, and thus differ from the mere mixtures of chromable azo compounds and chromium salts which cannot suitably be fixed by such a process. Four examples of the process are described in detail. (1,264,604; Apr. 30, 1918; Assigned to Badische A. & S. Fabrik.)

**Burner for Dwight-Lloyd Roaster.**—S. E. FRASER, of Port Pirie, South Australia, patents an improved burner for igniting the ore stream on a Dwight-Lloyd roaster shown in Fig. 4. It comprises a number of special refractory bricks strongly bound together with iron bars and rods and shaped to form a shallow, inverted elliptical dish. Blow torches 8 introduce a

FIG. 4—PLAN AND ELEVATION OF DWIGHT-LOYD ROASTER

flame tangently, and in operation the dish is filled with a swirling flame playing above the moving ore stream, heating by contact and radiation from the incandescent brick dish. Additional air may be introduced through openings like 15 as necessary. (1-262,580; Apr. 9, 1918.)

**Extraction of Resins and Turpentines.**—DAVID J. OGILVY, of Cincinnati, Ohio, patents an improvement over the usual methods for the extraction of resins

by digestion of woods with such solvents as petroleum distillates, pine oils, turpentine, etc. He employs a digester practically filled with conifer chips which is connected to a still set at a lower elevation and filled with a mixture of resin solvent and water. This mixture is heated and its vapors enter the bottom of the digester, extracting the resins, oleoresins and turpentine in the wood, which extracts are carried back into the still in the return condensate through the connection pipe. A reflux condenser is placed above the extractor to catch the uncondensed water and solvent passing up through the wood contained in the digester. When the operation is completed, the still containing the watery liquid and the resinous magma is connected with an exhaust condenser and a preliminary separation made of the resin solvents, turpentine and oils. The resinous magma and watery liquor remaining in the still are separated and the magma used for the production of resinous substances. The inventor claims that his process may be conducted at a lower temperature, and the continual presence of water vapor is an additional precaution against fire and explosion. The water and steam have a disintegrating action on the wood, allowing readier attack of the solvent, which itself is attenuated and used to maximum efficiency by the same agents. (1,264,551; April 30, 1918.)

**Arc Adjustment in Steel Making.**—WM. E. MOORE, of Pittsburgh, Pa., notes that it is desirable to use a long arc when melting solid metal in an electric furnace. This long arc gyrates over a large area, and local short circuits by molten metal are therefore not so troublesome. The high heat of such an arc is not particularly damaging to the furnace roof, since the unmelted metal absorbs radiations much more completely than after it is covered with a glassy slag. During the refining process, therefore, it is preferable to shorten the arc considerably. The inventor proportions the electrical circuits for the low voltage arcs of the refining cycle, and increases the voltage only during the melting stage, from say 40 or 60 volts up to 120 or 240. This practice reduces the size of the electrical conductors, switches, and other accessories, as well as bettering the power factor by reason of less self-inductance and counter electromotive force. The inventor also utilizes the rectified current produced during the furnace operation to heat the bottom just sufficiently to prevent formation of accretions and to stir the bath. He presents a number of wiring diagrams for different conditions of current and arrangements of electrodes. (1,242,464; Oct. 9, 1917.)

**Coke Oven.**—THEODOR VON BAUER of Germany patents a new coke oven constructed to operate on the regenerative principle and so arranged with combined

vertical and horizontal flues that the heat can be increased from the top of the retort downward. This prevents decomposition of the valuable by-products in their passage through a previously coked portion of the charge, and provides an increased heat for the denser bottom portions. In Fig. 5 preheated air from regenerator *u'* and gas from the main de enter the top horizontal flue *e*, passing into flue *g* through vertical passes *f*. Here the burning gases are mixed with more air and gas introduced through the heads of the oven walls. Entering flue *i* the hot gases receive further supplies of air and gas through a number of openings leading downward from a double channel *h*. In order to simulate surface combustion conditions, these gases—now containing an excess of combustible,

FIG. 5—REGENERATIVE COKE OVEN

pass into vertical flues *k* through the mass of broken chamotte *Sch* supported by perforated stones *St*. During this passage they receive the necessary air for combustion from the vertical flues *l* which conduct preheated all from regenerator *v* to the mass of chamotte. The hot gases then enter a sole channel *l* by the ports at the base of the vertical flues *k*, and thence pass through the regenerative flues *t* to the main culvert *C*. The inventor

FIG. 6. FLUES

points out that the oven may be connected to a by-product plant during the early part of the distillation in the usual manner, but as the gases evolved became leaner in valuable hydrocarbons, it may be conducted directly into heating flues *e* at either side of the chamber by the double row of staggered passages *s* placed between each charge hole *m*. Figure 6 shows one set of these flues; when the lean gas is to be burned without cleaning, the slide gates *Vm* are raised. (1,253,445; Assigned to Bernhard Zwilling of New York City; Jan. 15, 1918.)

**Air Distribution in Regenerative Checkerwork.**—J. E. HUBBELL, of Philadelphia, Pa., patents an improvement in coke ovens with vertical heating flues and with regenerators set longitudinally below, designed to preheat the air only. Each unit of the regenerator contains a double sole flue, one for withdrawing the

waste gases during the heating stage, and the other contains an air pipe perforated at intervals along its length which acts as a distributor when cold air is flowing upward. By proper design a very uniform flow of hot air may be admitted into each of the heating flues above the regenerator, there to combine with gas entering through a nearby nozzle. (1,254,007, Assigned to Louis Wilputte, New Rochelle, N. Y., Jan. 15, 1918.)

**Ore Cooling, Moistening and Feeding Table.**—A. H. RICHARDS, of Salt Lake City, Utah, patents the device shown in Fig. 7 for converting an intermittent feed from furnace or elevator into a continuous stream. The material, which may be hot, drops through hopper 9 near the center of the rotating plate 10, and is

FIG. 7

gradually mixed and worked to the outer edge by the rabbles 25. Opposite these rabbles is a water spray 28, allowing the ore to moisten and cool one half rotation before reaching the rabble blades. The whole is surrounded by a proper hood 8 and the plate is supported by a shaft passing through the enclosed gear box 21 of sufficient stiffness that rollers under the edge of the horizontal plate are unnecessary. (1,231,790; Assigned to American Smelting and Refining Co., July 3, 1917.)

**Refractories.**—R. R. ZELL, of Birmingham, Ala., patents the use of a local mineral product called "siliconite" in the manufacture of refractory brick. Siliconite is finely divided silica, probably formed by weathering of earlier deposits, and contains but small traces of lime and magnesia, and about 2.25 per cent of iron and aluminium oxides. This mineral is crushed and a properly sized product mixed with 5 per cent of aluminium hydrate, 5 per cent of dehydrated gypsum and moistened into a plastic mass with a 10 per cent caustic potash solution. The mass is then wet-pressed, baked at 500 deg. F., and is then ready for the mar-

ket without further burning. (1,244,275; assigned to Siliconite Refractories Co., Oct. 23, 1917.)

F. M. BECKET, of Niagara Falls, N. Y., patents the use of ordinary or special slags produced in the ferro-chromium furnace. These slags are essentially a  $MgO \cdot Al_2O_3 \cdot SiO_2$  complex containing lesser percentages of iron and chromium and their oxides. After crushing and sizing, the mass is moistened with water or dilute sodium silicate, shaped in a brick press, and air or furnace-dried at temperatures as required by the contemplated use. The moist mixture may also be tamped in place in the furnace and fired. This refractory has a low coefficient of expansion, a high heat conductivity, high softening point, and very resistant to alkalis and basic slags. (1,244,688; Assigned to Electro Metallurgical Co., Oct. 30, 1917.)

FRED A. JONES, of Lakewood, Ohio, notes that calcined dolomite cannot be used for repairing furnace linings as a substitute for calcined magnesite owing to the fact that the calcium oxide contained in the former tends to air-slack, reducing the lumps to a fine powdery material which will be swept out of the furnace by the draft. He proposes to protect the dolomite from moisture by covering each particle with a layer of slag. He crushes the dolomite to about  $\frac{1}{4}$  inch, and mixes it with 10 per cent by weight of flue dust—essentially fine iron ore, coke, and limestone—when the whole is suitably moistened and calcined at from 2000 to 2500 deg. F. in a rotary kiln. In this manner the  $CO_2$  is driven from the dolomite, and a thin film of impervious material fuses on the outside of each particle. Finely divided materials of the same nature when calcined as noted will produce agglomerated particles of substantially the same properties. (1,251,535; Jan. 1, 1918.)

**Electric Furnace Processes for Iron and Steel Manufacture.**—ERNEST HUMBERT, of Welland, Ontario, patents the process of making steel or pig iron by placing scrap irons of various origin in a hot electric furnace together with a predetermined amount of coke and flux. As soon as the lower portion of the solid charge attains incandescence, air is blown into the mass by a pipe, projecting downward through a door, and the end of the pipe adjusted from time to time so as to be kept just above the pool of melting metal. The inventor claims that the air blast removes the impurities very rapidly, and the melting time is largely reduced; the heat ends with refined, hot metal free from iron oxides ready to pour in from  $\frac{2}{3}$  to  $\frac{1}{2}$  the time of the older processes using electric energy only, with a corresponding increase in furnace and electrode capacity and life. (1,242,442, Oct. 9, 1917; and 1,252,443, Jan. 8, 1918.)

SAMUEL McDONALD, of Alhambra, Cal., patents the process of manufacturing steel in a tilting furnace, containing molten iron or steel, covered with a layer of molten iron ore. Downwardly inclining tuyeres in the rear blow a carbon-laden gas into the mixture at various depths, as the operator wills, by tilting the furnace. The carbon is absorbed by the steel, there to reinforce the reducing action of unabsorbed carbon on the molten oxide laying above and mixed into the metal by the stirring action of the blast. (1,255,191, Feb. 5, 1918.)

## Porcelain Pots for the Melting of Optical Glass

THE corrosive action of optical glass-melts and the high temperatures required to fuse them make it necessary to use pots both resistant to the action of the fused mass and sufficiently refractory to withstand the severe heat duty. At the same time it is desirable that the iron content of the pot mixture be so low that practically no contamination of the glass through this source occurs. This is particularly advisable in the fusion of barium glasses which are sensitive to the presence of iron oxide and readily assume a green color which is detrimental for photographic purposes. Since decolorizing is not permissible in making optical glass the importance of pure constituents and of pots as low in iron as possible is obvious. Experience has shown that the commercial pots are not suited for this work. The optical glass laboratory of the Bureau of Standards at Pittsburgh has realized the importance of special pots from the beginning of this work several years ago and has completed a series of experiments with the result that a mixture has been produced which resists even the extremely corrosive action of heavy barium crown glass, which so far has been found to destroy every kind of pot in which attempts have been made to melt it.

The composition in question is virtually a porcelain and in using the pots it is necessary to carry the temperature to about 1400 deg. C. before they are charged with the glass mixture. This will insure the vitrification of the body and with it the desired dense structure.

The composition which has given the best results is as follows:

|                                                                               | Per cent |
|-------------------------------------------------------------------------------|----------|
| White-ware pottery bisque, ground and screened to pass the 10-mesh sieve..... | 35       |
| Pot shell (from used porcelain pots).....                                     | 10       |
| Feldspar.....                                                                 | 3        |
| Potters flint.....                                                            | 4        |
| Tennessee ball clay.....                                                      | 15       |
| Illinois bond clay.....                                                       | 5        |
| Georgia kaolin.....                                                           | 8        |
| Florida kaolin.....                                                           | 8        |
| North Carolina or Maryland kaolin.....                                        | 12       |
|                                                                               | 100      |

The pottery bisque is the waste unglazed material which is rejected in the manufacture of white tableware. The supply of this bisque is ample for the needs of the pot makers supplying the optical glass manufacturers. For the purpose in question it is necessary to use only the so-called white-ware body and not porcelain, whether it be for table-ware, floor tile or electrical insulators which would not be sufficiently refractory.

At the Pittsburgh laboratory of the Bureau of Standards the production of glass pots by the casting process has also been developed very successfully, thus eliminating the use of skilled labor needed in making the pots by the usual building-up method. Here the body constituents, to which about 0.2 per cent of a mixture of sodium silicate and sodium carbonate has been added, are prepared to a thick but still fluid suspension which is poured into suitable plaster molds provided with a core. The plaster absorbs the water very readily and causes the mass to stiffen after about 16 hours when the core can be removed. The mold can be taken apart after about 24 hours. The pots thus

made have been found to dry very readily so that in many cases they can be placed in the furnace in from 4 to 6 weeks. This process ordinarily requires from

PLASTER MOLD FOR THE CASTING OF GLASS POTS

3 to 4 months. Cast pots have been made from the following composition:

|                                                 | Per cent |
|-------------------------------------------------|----------|
| White-ware pottery bisque, through 10-mesh..... | 48       |
| Tennessee ball clay.....                        | 15       |
| Illinois bond clay.....                         | 8        |
| Feldspar.....                                   | 5        |
| Georgia kaolin.....                             | 7        |
| Florida kaolin.....                             | 10       |
| North Carolina or Maryland kaolin.....          | 10       |
|                                                 | 100      |

The cast pots have proved very successful for the melting of optical glass and have been found to be superior to the hand-made ones owing to the uniformity of structure.

## A New Drying System for Liquids

**A**N interesting system for recovering the solid constituents of liquids in a dry, finely powdered form has been developed and is being introduced by Gerald A. Lough of 90 West St., New York. The system is simple and inexpensive and has been found very efficient.

The accompanying photograph shows one of these dryers installed in a tanning extract plant in Tennessee. The process is designated as the "air-blown process" and the equipment consists of a chamber constructed of masonry divided into two compartments, into the first of which the liquid to be evaporated is injected in a fine spray.

A current of hot air, furnished by direct-fire heating from the furnace at the right, is introduced below the spray, rises through it, absorbing its water content, and passes to the second, or dust-settling compartment. The bulk of the solid constituents of the liquid is deposited in the first compartment and the light flocculent particles in the form of fine dust in the second compartment.

A screw conveyor at the bottom of the chamber conveys the dried material from both compartments to a

EQUIPMENT FOR DRYING SOLUTIONS OR SUSPENSIONS

bucket elevator which raises the material to the storage bin at the left. From the bottom of this storage bin the material is bagged.

The advantages of the process are claimed to be low first cost and low upkeep, and considerable economy in drying owing in part to the fact that the heat is applied direct to the substance to be dried, and not by transmission through a metal membrane with consequent loss by radiation. The minute subdivision of the atomized fluid permits the heated air to surround each particle and absorb its watery envelope instantly. The liquid is projected into the chamber in such a way as to form a blanket of spray which fills the full transverse area of the chamber, so that to find an exit the hot air must pass through the spray and in consequence give up its heat.

Any product contained in solution, suspension or emulsion may be dried by this means to a fine, dry, flour-like product. Such substances as milk, eggs, malt extract and delicate chemicals may be reduced to their solid constituents by this means at high temperatures without

injurious effect. Whole or skimmed milk and eggs dried by this method are completely soluble in cold water.

The accessory apparatus—air heater, air compressor, motors, fan, dust collector and conveyors are all standard equipment, and the dryers are built on the job from plans designed for the customer's particular needs.

## Government Powder Plants Completed Ahead of Schedule

Operations in the Government's powder plants near Charleston, W. Va., and Nashville, Tenn., have begun two months ahead of schedule. The Nashville plant started June 4 and Daniel C. Jackling, Director of the United States Government Explosive Plants' Division, reported to Assistant Secretary of War Benedict Crowell that the Charleston plant started June 11. These two plants are beginning with the production of sulphuric and nitric acids, constituent parts in the manufacture of smokeless powder.

The \$120,000,000 allotted for the plants is expected to give the Government a smokeless powder production capacity equal to all other American plants combined. The War Department started preparations in the middle of January. A new division was organized, needs of the Army estimated and plans for the two plants were begun. As soon as sites were chosen, it was found necessary to build a new town on each site to house the employees. Approximately 9000 different buildings were erected. A staff of 500 engineers and architects laid out the plants.

Streets were put down and sewered, power plants constructed, and stores and hospitals erected. About 35,000 men worked on the construction of the plants. Probably 30,000 will be engaged in the actual production of powder.

When the task of building the plants was considered at the War Department last January, it was predicted that the production of powder might begin in August, barring unforeseen delays. Starting of the plants at this time insures their completion and full operation this year, or within less than twelve months of the date on which they were authorized.

## Importation of Chrome Ore and Chromite

In pursuance of the general policy of tonnage conservation, the War Trade Board have introduced restrictions upon the importation of chrome ore and chromite from overseas. The sources of home supply are numerous, and are believed to be capable of extensive development. To provide for interim demands, pending the further development of such deposits, imports from Cuba, Guatemala, Newfoundland and Brazil by sea will be permitted, not exceeding 43,500 tons up to March 31, 1919, and from New Caledonia up to 10,000 tons prior to December 31, 1918. Shipments overland or by lake from Canada, overland from Mexico, or as return cargo from European ports when coming from convenient ports and not involving delays in loading, will be permitted. All outstanding licenses for the import of chrome ore and chromite for overseas have been revoked as to shipments made after June 15, 1918.

## Book Reviews

**THE CHEMICAL ANALYSIS OF IRON**, by A. A. Blair, 313 pages, J. B. Lippincott Co., Philadelphia, Eighth Edition, 1918. Price \$5.00

The eighth edition of this well known work is presented in the same style as former editions. The old cuts have been used throughout with but few exceptions. The methods for the analysis of furnace and other gases have been omitted and a chapter added dealing with the analysis of alloy metals. Although the subject matter has been largely revised and rewritten the book is still open to some criticism.

In the introductory chapter descriptive of apparatus and reagents used in making iron analysis the classification of ammonium bisulphate,  $\text{NH}_4\text{HSO}_4$ , under "alkaline salts" and of barium hydrate under "salts of alkaline earths" will doubtless prove to be misleading to the beginner. In the chapter devoted to the determination of carbon by direct combustion it is disappointing to find no mention of the modern simplified methods in prevalent use and no illustrations of up to date combustion trains.

In the methods given for the determination of manganese mention has been omitted of the widely used titration with sodium arsenite of permanganic acid obtained by oxidation with ammonium persulphate in the presence of silver nitrate. The outline for the determination of nickel by titration with cyanide recommends an ether separation of the iron or the precipitation of nickel with dimethylglyoxime in place of the usual direct and rapid method of adding citric acid to eliminate the interference of iron.

The chapter on the analysis of alloy metals contains some excellent material. It is believed that this volume will be of more interest to the research chemist performing special analyses than to the routine steel works analyst. It contains some good outlines and will prove a valuable addition to reference libraries.

\* \* \*

**A TEXT BOOK OF INORGANIC CHEMISTRY**. Edited by J. Newton Friend, D.Sc., Ph.D. London: Charles Griffin and Company, Ltd.

**VOL. I: AN INTRODUCTION TO MODERN INORGANIC CHEMISTRY**. By J. Newton Friend, H. F. V. Little, and W. E. S. Turner. *THE INERT GASES* (Group O of the Periodic Table). By H. V. A. Briscoe, D.Sc. Second Edition, revised; large octavo (15 x 22 cm.), v + 385 pp.; price 10s. 6d. net (\$3.50 in U. S. A.).

**VOL. IV: ALUMINIUM AND ITS CONCENTRATIONS**, including the *RARE EARTH METALS* (Group III of the Periodic Table). By H. F. V. Little, B.Sc., Chief Chemist at Thorium, Ltd. Large octavo (15 x 22 cm.), xx + 485 pp., price 15s. net (\$5.00 in U. S. A.).

**VOL. V: CARBON AND ITS ALLIES** (Group IV of the Periodic Table). By R. M. Caven, D.Sc. Large octavo (15 x 22 cm.), xxi + 468 pp.; price 15s. net (\$5.00 in U. S. A.).

**VOL. VIII: THE HALOGENS AND THEIR ALLIES** (Group VII of the Periodic Table). By Geoffrey Martin, D.Sc., Ph.D., and Ernest A. Dancaster, B.Sc. Large octavo (15 x 22 cm.), xviii + 337 pp.; price 10s. 6d. net (\$3.50).

The title is something of a misnomer; the work is nearer to being a hand-book or small encyclopedia. It is similar in content to Moissan's "La Chimie Minérale." The plan is unique: each volume from I to IX takes up a successive group of the Periodic Table, thus bringing together in each volume the elements of one chemical family. Volumes II, III, VI, VII and IX are not yet issued.

Volume I is an up-to-date review of inorganic chemistry, followed by a 65 page section on the rare inert gases of Group O. There is not enough detailed explanation for a text-book, but it is a fine reference book, being particularly enriched by numerous foot-note references to the original sources of information. At places, however, the treatment is too scanty, e.g., the vapor pressure of solids is discussed in detail but not that of liquids; specific heats are handled

at length, but latent heat of change of state is not even mentioned. One suspects that there may be other omissions of important topics.

Volume IV on boron, aluminium gallium, indium, thallium, scandium, and the rare-earth elements is written in masterly style, particularly the second half devoted to the rare earths. Aluminium does not lend itself to condensed treatment as well as the other metals mentioned, and in this one instance the subject matter seems scanty and elementary; the other metals are relatively much more thoroughly handled, and in an entirely satisfactory manner which indicates the expert, master of his subject and enthusiastic in its presentation.

Volume V is concerned with carbon, silicon, titanium, tironium, thorium, germanium, tin and lead. The author was not equal to his task; in fact, he approached it with a dilettante air which spelled failure, he says in his preface "the group contains no element the study of which is quite so fascinating as that of, say, chromium or nitrogen; and, moreover, contains one element tironium, about which it would be difficult for any chemist to be enthusiastic." Starting with that totally unscientific attitude, an indifferent book followed of necessity; the author might have succeeded better if writing on chromium or nitrogen, but we have a right to doubt even that. The best chapter is that on thorium, and here the author had the assistance of Mr. Little, who wrote the fine treatise on the rare earths in Vol. IV, and who evidently keyed up this chapter to a proper scientific plane. The rest of the book is only "fair to middling."

Volume VIII appeared some time ago, and has already been reviewed in this *Journal*, Feb. 15, 1917, page 233.

The completion of the work as a whole will be a remarkable war-time achievement; the editor and publishers are to be congratulated on their enterprise and on the high average of success attained in the treatises.

**THE THEORY AND PRACTICE OF ORE DRESSING**.

By Edward S. Wiard, S.B. Octavo (15 x 23 cm.), viii + 426 pages, 254 illustrations; price \$4.00 net. McGraw-Hill Book Company, Inc.: New York.

The scope of the work is narrower than its title. It concerns ore-dressing as applied in the western part of the United States. The treatment is unequal and in many places unsatisfactory. Five pages only to the oil-flotation process is practical exclusion from the book; three pages to electrostatic separation seems pretty scant; eleven pages to magnetic concentration is surely insufficient. These three important methods are all squeezed into one small chapter of twenty pages at the end of the book, whereas one would judge their treatment deserving of several times that space. The Dorr thickener is dismissed with two lines, without any further description; in fact, concentration altogether takes up less than one-fourth of the book, while crushing takes up over one-half. Yet the book has many strong points: crushing is well and thoroughly handled; theory is mixed throughout in a skillful and instructing manner; the practical descriptions are clearly written and well illustrated. With some of its deficiencies made up in a revised edition, it should prove a welcome book to the Western mill-man.

## Personal

MR. G. MONTAGUE BUTLER, University of Arizona, has just been appointed Director of the Arizona State Bureau of Mines to fill the vacancy created by the resignation of C. F. Willis. He will continue to serve as Dean of the College of Mines and Engineering, which position he has held for three years. The new Director of the Bureau intends to lay greater emphasis upon geological investigations, and will soon begin to collect the data required for the preparation of a reconnaissance geological map of Arizona.

MR. WILLIAM B. COLVER, chairman of the Federal Trade Commission, who has been in charge of wood pulp and its

products, including paper, has been extended additional authority over the same commodities by the War Industries Board.

ALEX. L. FEILD, formerly assistant metallurgist in the Bureau of Mines, has entered the research department of the National Carbon Co., Inc., in Cleveland, Ohio, and is engaged in general high temperature and physical research. During his service with the Bureau of Mines, Mr. Feild completed the very important investigations on viscosity of iron blast furnace slags.

MR. WALTON C. GRAHAM, manager of the research department of The Great Western Sugar Co., Denver, visited Boston, New York and other Eastern centers following his attendance at the meeting of the Chemical Engineers at Gorham, N. H.

WM. H. HUBBARD, mechanical superintendent of the Balbach Smelting and Refining Company, Newark, N. J., has resigned to take a similar position at the Northport Smelting and Refining Co., Northport, Wash.

M. R. HULL has accepted the position of designing engineer for the Nevada Consolidated Copper Co., at McGill, Nev. Mr. Hull recently returned from the Ural Mountains, Siberia, with orders to proceed with the design of a new copper smelter for the Sissert Mining Co. The mines and smelter have since been seized by the Bolshevik government, however, and the managing director, MR. NORMAN C. STINES, is lost and reported to be a prisoner in Germany. These facts, together with the impossibility of transferring funds, have necessitated the abandonment of the unfinished work.

MR. MILO W. KREJCI has resigned from the position of assistant superintendent of the Boston and Montana Reduction Works of the Anaconda Copper Mining Company, Great Falls, Montana, to enter consultation practice, and will be succeeded by J. O. Elton, formerly superintendent of the zinc refinery. Mr. Krejci retires after a service of nearly twenty years, during which time he had superintended nearly every department of the plant. As metallurgist his influence on the development of the 20-foot converter and other Great Falls contributions to the metallurgy of copper was very strong. Recently he has been largely interested in the electrolytic copper and zinc refineries, and has studied the possibilities of making brass in electric furnaces very exhaustively.

CHARLES R. KUZELL has resigned from the staff of the Anaconda Copper Mining Company to assume a position at the United Verde Smelter at Clarkdale, Ariz. MR. KUZELL was superintendent of reverberatory smelting at the Washoe Reduction Works.

MR. B. F. LAFOLETTE, who has had charge of the Engineering, Sales and Advertising Departments for the Clarage Fan Company, Kalamazoo, Mich., has resigned to get into Government Service, July 1. He will be located in either Philadelphia or Washington as an engineer with the Requirements Division of the U. S. Shipping Board.

PROF. S. K. LOY, Professor of Chemistry at the University of Wyoming, Laramie, Wyo., has accepted the position of chief chemist with the Midwest Refining Company, Casper, Wyoming.

MR. CHAS. H. MACDOWELL has presented his resignation as a member of the Committee on Fertilizers of the Chemical Alliance, stating that on account of his duties on the War Industries Board he found it impossible to attend the meetings. MR. DEWITT BROWN of Chicago was unanimously elected to succeed Mr. MacDowell.

MR. A. G. MCGREGOR has returned to Warren, Arizona, from a trip to South America, where he is supervising the construction of a new plant for the Cerro de Pasco Copper Corporation.

MR. ALEXANDER ORSCHEFSKY has been made supervisor of the analytical laboratory of the Chrome Plant of the Metal & Thermite Corporation, superseding MR. ABRAHAM L. KONWISER, who resigned.

MR. HERMAN F. SCHOLTZ, assistant chief engineer of the Newport Hydro Carbon Company, and the Newport Chemical Works, Inc., at Carrollville, Wis., has been assigned to active duty as Captain in the Engineer Officers Reserve.

## Obituary

MR. C. B. SPRAGUE, chief chemist for the United States Smelting, Refining and Mining Company, died at Salt Lake City, Utah, June 8, from injuries received three days earlier when a speeding automobile in which he was riding struck a fire plug. All the occupants of the machine except the driver also met their death. Mr. Sprague was born in Salt Lake City on Nov. 23, 1875, and attended the University of Utah. He had been employed by the United States Company since 1906, during which time he had paid particular attention to the action of smelter smoke on vegetation and live stock. He was widely known on account of his process of using volatile basic oxides to neutralize sulfuric acid anhydride in smelter gases before bag-housing. This process has been used in the Midvale and Mammoth plants of his own company, and the Murray and Perth Amboy plants of the A. S. & R. Co.

DR. WILLIAM B. PHILLIPS, geologist, died at his home in Houston, Tex., on June 7, aged 61 years. He was born in 1857 at Chapel Hill, N. C., and was educated at the University of North Carolina, where both his father and grandfather had been teachers. Upon his graduation, when he was 20 years old, he went to Saxony, where he studied at the Freiberg School of Mines. For a time after obtaining his degree, he was employed as chemist at the North Carolina Experiment Station. Later, from 1886 to 1888, he taught agricultural chemistry and mineralogy at the University of North Carolina, following in his father's steps. From 1888 to 1892 he practiced as a mining engineer at Birmingham, Ala. During this time he accepted a position in chemistry and metallurgy at the University of Alabama, which he held for two years, then becoming chemist for the Tennessee Coal, Iron and Ry. Co. At this period, he also served on the staff of the *Engineering and Mining Journal*. In 1901 he became director of the University of Texas mineral survey, remaining until 1905, when he again took up private work. In 1909 he was called to take charge of the newly created bureau of economic geology and technology at the university. He resigned this position in 1914 to take the presidency of the Colorado School of Mines, which office, however, he gave up a year later, preferring private practice. He was the author of about 300 scientific and technical articles. Dr. Phillips was a member of the American Institute of Mining Engineers. He was a Mason and a member of the Phi Beta Kappa and Phi Kappa Sigma fraternities.

## Current Market Reports

### Non-Ferrous Metal Market

**Tuesday, June 25.**—Prices have a tendency to rise except where the government has fixed set rates.

**Aluminum:**—The government price is 33c. a pound f.o.b. plant in 50-ton lots, 33.1c. down to 15-ton lots, and 33.2c. in lots down to 1 ton.

**Antimony:**—Good buying has prevailed and dealers are quoting firm in the range of 13% @ 13%.

**Chrome:**—Producers have established a schedule on the basis of \$1.30 per unit ore.

**Copper:**—Distribution of copper on the basis of 23½c. to consumers and 24.67½c. to dealers continues by the producers' committee.

**Lead:**—With the reaching of a price agreement on lead by the producers' committee last week, speculation is eliminated for the duration of the war. The New York basis will be 7.82½c. and East St. Louis, 7.75c.

**Manganese:**—Variable ton unit scale price, 40 per cent \$1.10, 50 per cent \$1.20. For full specifications see METALLURGICAL AND CHEMICAL ENGINEERING, page 629, June 15.

**Molybdenum:**—Quoted at \$1.25 per pound for 90% molybdenum sulphide.

**Spelter.**—Exceptionally strong conditions have ruled the market for prime Western spelter during the past few days and new high prices have been made. Spot New York 8.25 @ 8.37½c. and East St. Louis at 8.20 @ 8.30c.

**Tin.**—Much interest was manifested by the plan of the government to fix the price of tin. To do this the co-operation of the British, Dutch and Chinese governments will be essential and it is improbable that the latter two will agree; 81c. per lb. for August and September deliveries has been quoted, 90 to 95c. normal. Most of the shipments are coming in via the coast with high freight rates.

**Tungsten.**—The highest grade material containing no tin, no copper, low manganese and over 70% WO. has brought \$24.00 per ton unit. Impure material has sold as low as \$19.00.

|                                     |           |
|-------------------------------------|-----------|
| Bismuth .....                       | \$ 3.50   |
| Cadmium .....                       | 1.40-1.50 |
| Nickel .....                        | .40       |
| Silver .....                        | .994      |
| Platinum, oz. ....                  | 105.00    |
| Palladium, oz. ....                 | 135.00    |
| Cobalt .....                        | 2.50-3.50 |
| Magnesium .....                     | 1.75-2.00 |
| Quicksilver, California (75 lb.) .. | 125.00    |
| Mexican (75 lb.) ..                 | 118.00    |

### The Iron and Steel Market

By announcement of June 24 the War Industries Board has continued for another three months, or through September 30, the set prices for pig iron, unfinished steel and finished steel products. Lake Superior iron ore is advanced 45 cents per ton. Various arguments had been presented that there should be advances in one product or another, but the War Industries Board, undoubtedly in collaboration with the Federal Trade Commission, which has complete cost data from all makers, was quite indisposed to make any changes except in the downward direction, and was particularly desirous of avoiding any change that would disturb the present smooth working of things.

The exception made in the case of Lake Superior iron ore was due to the combination of facts that the ore must, beginning June 25, pay advanced rail freights equal to 30 cents per net ton, equal to 33.6 cents per gross ton, although as a matter of fact rates as revised are taken at the nearest ten cent multiple, and that the cost of mining has so advanced, since the expiring ore prices were originally made, November 23, 1916, that the ore producers are in no position to pay the freight advance. It is purely an incident, moreover, that the ore interests were called upon to pay the freight advance in the first place, this being due to the fact that the original freight advance order required that the ore freight advance be paid upon the first haul of the iron ore, while custom has it that Lake Superior iron ore prices are made at Lake Erie dock, and practically all the ore must pay the advance to get to lake water.

The ore advance plus the advanced freight rates on coke, limestone and other supplies, cause an increase in the cost of making a ton of pig iron, at the typical northern furnaces, of more than \$1.50. This, however, tends to offset the fact that the authorities at Washington have always considered the pig iron basis, \$33, a trifle too high, their original idea having been \$30.

### PITTSBURGH BASIS RESTORED

As noted above, the existing set maximum prices for unfinished and finished steel were continued. One change, however, is made. Bars, shapes and plates, at 2.90c., 3c. and 3.25c., respectively, are set purely on a Pittsburgh basis, the separate Chicago basing point being eliminated. When the original price announcement was made, September 24, 1917, the bar, shape and plate prices were announced as f.o.b. Pittsburgh or Chicago, greatly to the surprise of the trade. Only in times of exceptionally sharp competition in finished steel products, when the market was quite disorganized, have additional basing points been considered or recognized in actual transactions, and for a stable market, such as it is especially desired by all should obtain at this time, the single basing point is virtually a *sine qua non*.

That the great majority of iron and steel producers have been making large profits, and will continue to make large

profits, with the set prices continued, goes without saying. The argument that there are some small producers whose costs are exceptionally high has resulted in no action by the War Industries Board, either because the reports to the Federal Trade Commission did not disclose important cases of that description, or from the practical consideration that if a producer's costs are high it is usually because there is an excessive employment of labor or raw materials, the very elements in which there is a scarcity that is restricting to some extent the production of pig iron and steel. The practical thing if such a condition existed would be to release the labor and raw materials that are being wastefully employed, and use them efficiently elsewhere.

### DISTRIBUTION

The system of distribution of pig iron and steel products to the more essential commercial industries is proceeding quite smoothly. The "schedule of purposes entitled to preference treatment" was promulgated by the War Industries Board's resolutions of June 6, referred to in last report. A revised schedule was promised, but is not yet promulgated. The merchant furnaces and steel mills are finding no particular difficulty in interpreting the regulations, and any doubtful cases can readily be referred to Washington.

The regulations are proving not nearly as drastic as they have been painted, for the simple reason that the demand, or requirements, left out represents a relatively small tonnage, generally estimated at less than 10 per cent of the production. From this it becomes evident that if, after all priorities, allocations and preferences are taken care of there is any pig iron or steel left, it would not require a great deal to produce an actual surplus.

That the war requirements are going to be met fully in all directions is now evident, provided there is no serious curtailment in production from the rate of the past three months. Of all the war requirements the greatest doubt existed in the case of plates for shipbuilding, and yet with shipbuilding speeded up and looking forward to still greater activity, the Director General of Shipbuilding has testified before a congressional committee that he has no uneasiness as to the supply of steel for shipbuilding, his concern being as to accessories, first engines, second boilers and afterwards a variety of minor accessories. All the plans for the war activities contemplate the accumulation, if possible, of surpluses of steel as a measure of safety.

### PRODUCTION

Production of pig iron and steel ingots has been at a slightly greater rate than that of May, when there was a slight improvement, over April, in pig iron, but a slight loss in ingots. The weather on the whole has been a trifle more favorable. July and August are expected to witness considerable shrinkage, but every effort is being made in the industry to curtail the shrinkage that in past summers has been regarded as altogether unavoidable. Labor is scarce, but the scarcity has not interfered greatly with production, and some hopes are entertained that labor conditions may be improved by the regulation now undertaken by the Department of Labor, whereby employers are to avail themselves of the recently established governmental employment agencies and are expected to refrain from paying bonuses or "privatizing" in other ways upon the working forces of other employers.

### Chemical Market

**HEAVY CHEMICALS.**—The latter part of the period of the last two weeks has shown considerable lack of activity with a few transactions worthy of note while in matter of price there have developed advances in a few directions with a shading off in others. In most instances however the tendency has been upward.

**Bichromate of Soda.**—There has been a continued activity in this item on substantial demand. Actual sales of spot material have been made at 27½c. but up to 28c. was the last reported general trading level. Sizable quantities have been difficult to locate probably because stocks are in very strong hands who have chosen to sit back and await developments of the upward trend.

**Soda Ash:**—The market has been quiet but actual buyers are reported as having paid 2.90. The general market is asking 3c. to 3.05. Bags from dock were available in a small way at 2.20 but from warehouse, one car was reported as selling at 2.35, which is the generally quoted figure for important business.

**Sulphuric Acid:**—Quite in line with the general prophecies made at the time of our last report there has developed a shortage in this material accompanied by an appreciation in prices. The 66% brimstone is being offered in tank car lots at 37.50 with quotations from some directions of 40.00. In drums 40.00 and 42.00 are quoted with drums extra. The 60% is being offered in certain directions only for delivery in tank car quantities at 27.00 and there is very little to be obtained, some producers having already stopped quoting.

**Caustic Soda:**—Buyers have been showing very little interest and the result has been a decline in price asked on rolling material. The last reported on this type of business was 4c. with material from dock at 4.15 and from warehouse at 4.20 although these prices were considered a little low as the regular traders are quoting from 4.25 to 4.50 on standard brands.

**Yellow Prussiate of Soda:**—There has been a continued depreciation in price with material rolling to New York available at 61c. and 61½c. Spot prices quoted range from 62 to 64c. Sellers are showing more firmness in light of a renewed inquiry in the last few days.

**Glycerine:**—The first transaction for a lengthy period was made at 62c., covering about ten cars of dynamite material. Sales of the soap lye, loose, have been noted at 44c. and 46c.

**COAL TAR PRODUCTS:**—Offerings of most materials have been plentiful but the market has been quiet with a slight falling off in some instances from prices last quoted on a few items. The general tendency however is toward advance also in these materials.

**Formaldehyde:**—It is understood that restriction has been placed on this material by the government with a setting of a price of 16¼c. works and 16½c. New York. The latest reports disclose offerings of resale material at 17c. in one direction.

**Benzol:**—This market is fast approaching gasoline prices which brings this fuel again into serious consideration as a substitute. Large producers are willing to accept 23c. in tank car lots and from other directions material in drums is being quoted at 26 and 27c.

**Phenol:**—The developments have been interesting in spite of the report that the government has purchased 1,000,000 tons for picric acid manufacture. Export licenses for shipment of material to the Far East have been granted and some of the English phenol has been received in this country. In export drums the price was 47c. and for domestic drums 48c. is the general level.

**Toluol:**—Dye manufacturers are said to be receiving continual releases at the government price of 1.50 for tanks and 1.55 for drums. Resale material is now seldom heard of and then usually in single drum offers.

**Hydroquinone:**—One of the most favored makes is said to be purchasable at 2.65 through second hands but from 2.75 to 3.00 is the generally quoted range.

**Benzoate of Soda:**—There has been slight inquiry with a depreciation in price to the generally quoted level of from 3.15 to 3.25 for the toluol product. Manufacturers using the benzol process are quoting from 3.00 to 3.25, depending upon quantity.

**Benzoic Acid:**—The acid is showing a firm tone with quotations on the basis of from 3.45 to 3.70 for the acids from both the toluol and benzol processes.

**Metatoluenediamine:**—Very little is being offered so far as can be learned and it is reported that the leading producers are sold ahead. Last sales reported were on the basis of from 1.85 to 2.00.

**Aniline Oil:**—Manufacturers are not meeting the prices asked for resale material and are holding at 27 and 28c.

## General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET, JUNE 26, 1918

|                                                      |         |               |        |

## Coal Tar Products (Crude)

|                                        |                    |      |   |       |
|----------------------------------------|--------------------|------|---|-------|
| Benzol, pure, water white              | gal.               | .23  | — | .26   |
| Benzol, 90 per cent                    | gal.               | .25  | — | .25   |
| Toluol, in tank cars                   | gal. (Fixed Price) | 1.50 | — |       |
| Toluol, for non-military use, in drums | gal. (Fixed Price) | 1.55 | — |       |
| Xylol, pure, water white               | gal.               | .45  | — | .55   |
| Solvent naphtha, water white           | gal.               | .17  | — | .22   |
| Solvent naphtha, crude, heavy          | lb.                | .13  | — | .16   |
| Cresosote oil, 25 per cent             | gal.               | .40  | — | .55   |
| Dip oil, 20 per cent                   | gal.               | .30  | — | .32   |
| Pitch, various grades                  | ton                | 8.00 | — | 20.00 |
| Carbolic acid, crude, 95-97 per cent   | lb.                | 1.05 | — | 1.10  |
| Carbolic acid, crude, 50 per cent      | lb.                | .60  | — | .65   |
| Carbolic acid, crude, 25 per cent      | lb.                | .35  | — | .38   |
| Cresol, U. S. P.                       | lb.                | .18  | — | .20   |

## Intermediates, Etc.

|                                |     |       |   |       |
|--------------------------------|-----|-------|---|-------|
| Alpha naphthol, crude          | lb. | 1.00  | — | 1.10  |
| Alpha naphthol, distilled      | lb. | 1.60  | — | 1.70  |
| Alpha naphthylamine            | lb. | .60   | — | .65   |
| Aniline oil, drums extra       | lb. | .25   | — | .36   |
| Aniline salts                  | lb. | .34   | — | .36   |
| Anthracene, 60 per cent        | lb. | .50   | — | .65   |
| Benzaldehyde (f.f.c.)          | lb. | 3.65  | — | 2.00  |
| Benzenide, base                | lb. | 1.75  | — | 2.60  |
| Benzenide, sulphate            | lb. | 1.40  | — | 1.50  |
| Benzoic acid U. S. P.          | lb. | 3.45  | — | 3.70  |
| Benzonate of Soda, U. S. P.    | lb. | 3.00  | — | 3.25  |
| Benzyl chloride                | lb. | 2.30  | — | 2.50  |
| Beta naphthol benzoate         | lb. | 10.00 | — | 12.00 |
| Beta naphthol, sublimed        | lb. | .85   | — | .90   |
| Beta naphthylamine, sublimed   | lb. | 2.65  | — | 3.10  |
| Dichlor benzol                 | lb. | .12   | — | .20   |
| Diethylaniline                 | lb. | 5.00  | — | 5.00  |
| Dinitro benzol                 | lb. | .35   | — | .40   |
| Dinitrochlorobenzol            | lb. | .40   | — | .42   |
| Dinitrophenathaline            | lb. | .60   | — | .70   |
| Dinitrotolul                   | lb. | .60   | — | .65   |
| Dinitrophenol                  | lb. | .46   | — | .50   |
| Diethylaniline                 | lb. | .75   | — | .80   |
| Diphenylamine                  | lb. | 1.00  | — | 1.10  |
| H-acid                         | lb. | 2.30  | — | 3.00  |
| Metaphenylenediamine           | lb. | 1.75  | — | 2.00  |
| Monochlorbenzol                | lb. | .17   | — | .20   |
| Naphthalene, flake             | lb. | .094  | — | .104  |
| Naphthalene, balls             | lb. | .104  | — | .104  |
| Naphthalene acid, crude        | lb. | 1.20  | — | 1.30  |
| Naphthylamine-di-sulphate acid | lb. | 1.00  | — | 1.10  |
| Nitro naphthaline              | lb. | .45   | — | .50   |
| Nitro toluol                   | lb. | .60   | — | .65   |
| Ortho-amidophenol              | lb. | .15   | — | .18   |
| Ortho-dichlor-benzol           | lb. | .15   | — | .18   |
| Ortho-toluidine                | lb. | 1.00  | — | 1.25  |
| Ortho-nitro-tolul              | lb. | .75   | — | .80   |
| Para-amidophenol               | lb. | 4.00  | — | 4.25  |
| Para-amido-phenol, H. Ch       | lb. | 4.00  | — | 5.00  |
| Para-dichlor-benzol            | lb. | .12   | — | .15   |
| Paranitraniline                | lb. | 1.60  | — | 1.70  |
| Paranitro-tolul                | lb. | 1.50  | — | 1.60  |
| Paraphenylenediamine (base)    | lb. | 3.50  | — | 4.00  |
| Para toluidine                 | lb. | 2.50  | — | 2.25  |
| Phthalic acid anhydride        | lb. | 3.00  | — | 4.48  |
| Phenol, U. S. P.               | lb. | .47   | — | .48   |
| Resorcin, technical            | lb. | 5.00  | — | 6.00  |
| Resorcin, pure                 | lb. | 8.00  | — | 9.00  |
| Salicylic acid                 | lb. | .90   | — | .90   |
| Salicylic acid                 | lb. | 1.90  | — | 2.00  |
| Sulphanilic acid, crude        | lb. | .30   | — | .32   |
| Tolidin                        | lb. | 2.50  | — | .50   |
| Toluidine-mixture              | lb. | .85   | — | .90   |

## Petroleum Oils

Crude (at the Wells)

|                        |      |      |   |  |
|------------------------|------|------|---|--|
| Pennsylvania           | bbl. | 4.00 | — |  |
| Corning, Ohio          | bbl. | 2.85 | — |  |
| Summit, Ky.            | bbl. | 2.60 | — |  |
| Wagoner, Ohio          | bbl. | 2.68 | — |  |
| Indiana                | bbl. | 2.28 | — |  |
| Illinois               | bbl. | 2.22 | — |  |
| Oklahoma and Kansas    | bbl. | 2.25 | — |  |
| Caddo, La., light      | bbl. | 2.25 | — |  |
| Corsicana, Tex., light | bbl. | 2.25 | — |  |
| California             | bbl. | 1.25 | — |  |
| Gulf Coast             | bbl. | 1.35 | — |  |

| Fuel Oil       |      |      |   |      |
|----------------|------|------|---|------|
| New York       | gal. | .11  | — | .11  |
| Pittsburgh     | gal. | .073 | — | .10  |
| Oklahoma-Kans. | bbl. | 1.56 | — | 2.75 |
| Texas          | bbl. | 1.85 | — | 2.35 |
| Los Angeles    | bbl. | 1.60 | — |      |
| San Francisco  | bbl. | 1.60 | — |      |

## Gasoline (Wholesale)

|               |      |      |   |  |
|---------------|------|------|---|--|
| New York      | gal. | .24  | — |  |
| Boston        | gal. | .25  | — |  |
| Pittsburgh    | gal. | .28  | — |  |
| Chicago       | gal. | .224 | — |  |
| Oklahoma      | gal. | .23  | — |  |
| San Francisco | gal. | .20  | — |  |

## Lubricants

|                                              |      |     |   |     |
|----------------------------------------------|------|-----|---|-----|
| Black, reduced, 29 gravity, 25-30 cold test. | gal. | .22 | — | .24 |
| Cylinder, light                              | gal. | .36 | — | .38 |
| Cylinder, dark                               | gal. | .37 | — | .38 |
| Paraffine, high viscosity                    | gal. | .40 | — | .41 |
| Paraffine, 903 sp. gr.                       | gal. | .36 | — | .38 |
| Paraffine, 885 sp. gr.                       | gal. | .26 | — | .28 |

## Flotation Oils

(Prices at New York unless otherwise stated)

|                                                                     |      |     |   |     |
|---------------------------------------------------------------------|------|-----|---|-----|
| Pine oil, crude, f. o. b. Florida                                   | gal. | .44 | — | .58 |
| Pine oil, steam-distilled, sp. gr. 0.925-0.940                      | gal. | .49 | — | .50 |
| Pine oil, destructively distilled                                   | gal. | .49 | — | .50 |
| Pine-tar oil, sp. gr. 1.025-1.035                                   | gal. | .35 | — |     |
| Pine-tar oil, double refined, sp. gr. 0.965-0.990                   | gal. | .40 | — |     |
| Pine-tar oil, ref., light, sp. gr. 0.970, tank cars, f. o. b. works | gal. | .37 | — |     |
| Pine-tar oil, ref., heavy, sp. gr. 1.025, tank cars, f. o. b. works | gal. | .28 | — |     |
| Pine-tar oil, ref., thin, sp. gr. 1.060-1.080                       | gal. | .32 | — |     |
| Turpentine, crude, sp. gr. 0.870-0.900                              | gal. | .40 | — |     |
| Hardwood oil, f. o. b. Michigan, sp. gr. 0.960-0.990                | gal. | .23 | — |     |
| Hardwood oil, f. o. b. Michigan, sp. gr. 1.06-1.08                  | gal. | .23 | — |     |
| Wood creosote, ref. f. o. b. Florida                                | gal. | .31 | — |     |

## Vegetable and Other Oils

|                          |      |      |   |       |
|--------------------------|------|------|---|-------|
| China wood oil           | lb.  | .26  | — | .27   |
| Cottonseed oil, crude    | lb.  | .21  | — | .22   |
| Linseed oil, raw, cars   | gal. | 1.60 | — |       |
| Peasut oil, crude        | gal. | 1.36 | — | 1.364 |
| Rosin oil, first run     | gal. | .41  | — | .43   |
| Rosin oil, fourth run    | gal. | .63  | — |       |
| Soya bean oil, Manchuria | lb.  | .18  | — |       |
| Turpentine, spirits      | gal. | .75  | — |       |

## Miscellaneous Materials

|                                     |         |         |   |         |
|-------------------------------------|---------|---------|---|---------|
| Barytes, floated, white, foreign    | ton     | 38.00   | — | 42.00   |
| Barytes, floated, white, domestic   | ton     | 32.00   | — | 36.00   |
| Beeswax, white, pure                | lb.     | .62     | — | .64     |
| Casien                              | lb.     | .15     | — | .20     |
| Chalk, light, precipitated, English | lb.     | .15     | — | Nominal |
| China clay, imported, lump          | ton     | 17.50   | — | 36.00   |
| China clay, domestic, lump          | ton     | 12.50   | — | 20.00   |
| Feldspar                            | ton     | 8.00    | — | 12.00   |
| Fluorspar, gravel, f. o. b. mines   | ton     | 30.00   | — |         |
| Fuller's earth, powdered            | 100 lb. | 1.00    | — | 1.50    |
| Graphite, flake                     | lb.     | .15     | — | .18     |
| Ozokerite, crude                    | lb.     | Nominal | — |         |
| Ozokerite, American, refined, white | lb.     | Nominal | — |         |
| Red lead, dry, carloads             | lb.     | .10     | — | .114    |
| Rosin, 280 lb                       | bbl.    | 10.90   | — |         |
| Saponstone                          | ton     | 1.00    | — | 12.50   |
| Talc, American, white               | ton     | 15.00   | — | 22.00   |
| White lead, dry                     | lb.     | .094    | — | .104    |

## Plant Construction—Catalogs—New Publications

### Construction and Operation

#### Alabama

**ASHLAND**—The Empire Graphite Co. will rebuild its plant recently destroyed by fire with a loss of \$50,000.

**BIRMINGHAM**—The Ingalls Iron Works, Avenue D and Seventh St., will build a steel frame addition to its plant. Estimated cost, \$9,500.

#### Arkansas

**FORT SMITH**—The Arkansas Mining & Mercantile Co. will build a 200-ton concentration plant and its zinc and lead mine located between Boone and Marion Counties. Estimated cost, \$60,000. The company is in the market for drills, sludge and slime tables, engines, boilers, compressors, ore crushers, track, cars, belts and mill hardware. F. A. Handien, president and manager.

**ROGERS**—The Lenk Pat. Mining Co., Joplin, Mo., will build a concentration and stamp mill here and is in the market for crushers, rollers, sludge and slime tables, engines, boilers, etc. Estimated cost, \$100,000. P. Cleburn, Joplin, 530 Main St., Joplin, Mo., superintendent.

**ZINCO**—The Consolidated Zinc Mines Co., Dallas, Tex., will build a 400-ton concentration plant here. The company is in the market for sludge and slime tables, ore cars, scales, etc. Estimated cost, \$70,000. N. W. Palmer, Muskogee, Okla., superintendent.

#### Colorado

**LEADVILLE**—The Royal Tiger Mining & Milling Co. will build a 300-ton milling plant on its property in Swan Valley, north of Breckenridge.

#### Connecticut

**BRIDGEPORT**—Until July 11th, by Sewer and Paying Commission, building sewage disposal plant on Bostwick Ave.

**NEW HAVEN**—The United States War Department, Washington, D. C., will build a plant for the production of tolol from gas, to be located near the works of the New Haven Gas Co., on East Chapel St. Estimated cost, \$110,000. H. Koppers, Union Arcade, Pittsburgh, Pa., has charge of the work.

#### Illinois

**EPORIA**—The Peoria Tractor Co., 1100 West Washington St., has purchased a site on East Washington St. and will build a factory for the manufacture of machines.

#### Indiana

**WHITING**—The city plans to build a water filtration plant of 4,000,000 gal. daily capacity. Estimated cost, \$130,000. S. A. Greely, 64 West Randolph, Chicago, Ill., engineer.

#### Iowa

**CEJAR RAPIDS**—The La Plant Choate Steel Co., c/o E. W. La Plant, 1804 Bever Ave., has awarded the contract for the construction of a brick and mill construction factory, to Looms Bros. Perpetual Building.

**OTTUMWA JUNCTION**—The Chicago, Milwaukee & St. Paul Ry. Co. F. Loweth, chief engineer, Railway Exchange Building, Chicago, Ill., will build pumping station and filter plant of 70,000 gal. capacity, including pipe line and tank, which is a part of the new terminal facilities to cost, \$50,000.

#### Kansas

**BADGER**—The Badger Mining & Development Co., 103 Mines Bank Building Joplin, Mo., will build a 150-ton concentration plant on their 210 acre lease here and are in the market for sludge and slime tables, ore crushers, etc. Estimated cost, \$60,000. T. E. Forester, superintendent.

**BAXTER SPRINGS**—The Big Lead Mining Co., Muskogee, Okla., will build a

concentration plant here. Estimated cost, \$75,000. J. E. Hoshal, superintendent.

**BAXTER SPRINGS**—The Cortez Mining Co., Jefferson City, Mo., will build a 250-ton concentration mill and a 125-H. P. power plant requiring sludge and slime tables, motors and crushers. Estimated cost, \$68,000.

**BAXTER SPRINGS**—The Quaker Valley Mining Co. will build a concentration plant requiring crushers, engine, oilers and sludge tables. Estimated cost, \$50,000. W. W. Wakeman, superintendent.

**NEWTON**—The city plans to build sewage disposal plant consisting of pump house and pumps, imhoff tank, sprinkling filter, secondary settling tank and sludge filter, with connection sewers, manholes, etc. Black & Veatch, 502 Interstate Building, Kansas City, Mo., engineers.

#### Kentucky

**LEXINGTON**—The Lexington Roller Mills Co., 133-135 Broadway, has awarded the contract for the construction of a brick addition to its corn and flour mill, to Combs Lumber Co., 439 East Main St. Estimated cost, \$10,000.

**LOUISVILLE**—The Magic Keller Soap Co., 2745 Stokers St., has awarded the contract for the construction of a 4-story brick factory, to the National Concrete Construction Co., Board of Trade Building. Estimated cost, \$50,000.

#### Maryland

**FORT MCHENRY**—The Cantonment Division, War Department, Washington, D. C., will build a chemical laboratory at the general hospital here. About \$152,000, cost plus percentage.

**INDIAN HEAD**—The Bureau of Yards and Docks, Navy Department, Washington, D. C., will remodel its chemical laboratory here. Estimated cost, \$20,000.

#### Michigan

**DETROIT**—The J. E. Bolles Iron & Wire Works, Milwaukee Ave., between Hastings and Crystal Sts., has awarded the contract for the construction of a one-story, brick addition to its factory to Walbridge-Aldinger Co., 2356 Penobscot Building.

**GRAND RAPIDS**—The Rudy Furnace Co. has awarded the contract for the construction of another plant here to Byers Construction Co., Kalamazoo. Estimated cost, \$50,000.

#### Missouri

**JOPLIN**—The Kirkwood Mining Co., Room 12, Cunningham Building, will build a 150-ton concentration plant, requiring sludge tables, motors and crushers. Estimated cost \$40,000. S. A. Smith, general manager.

**JOPLIN**—The Klein & Stern Investment Co., Frisco Building, will build a 150-ton concentration plant requiring sludge and slime tables, crushers, belts, engines, etc. Estimated cost, \$25,000.

**JOPLIN**—The Miami Yellville Mining Co., West Seventh St., will remodel its concentration plant and install new machinery. Estimated cost, \$25,000. J. Taylor, c/o Liberty Theater, superintendent.

**JOPLIN**—The Muskogee Lead & Zinc Co. will build a 300-ton concentration mill requiring sludge tables, conveyors, air compressors. Estimated cost, \$58,000. E. C. Beatty, Springfield, manager.

**JOPLIN**—The New Carolyn Metal Co. has purchased the Nescho Granby Metal Co., and will build a new 300-ton mill and increase the capacity of the present 150-ton mill to 300-ton. The company is in the market for sludge tables, slime tables, crushers, air compressors, engines and boilers. Estimated cost, \$100,000. Nels Darling, Oklahoma City, Okla., superintendent.

**JOPLIN**—Paeffle & Keller, West Fourth St., will build 150-ton concentration plant at its mine. Estimated cost, \$25,000. W. Paeffle, Fourth and North Pearl Sts., superintendent.

**JOPLIN**—Piachard & Clear Mining Co., Cunningham Building, will remodel its concentration plant at its mine and also install new machinery. Estimated cost, \$26,000. Fletcher Clear, Joplin, superintendent.

**KANSAS CITY**—The Jensen-Salsberry Laboratories, 1320 Main St., will build a 3-story, 28 x 128 ft., reinforced concrete and brick laboratory. E. O. Brostrom, 212 Reliance Building, architect.

#### Nebraska

**LINCOLN**—The State Board of Control, J. S. Dales, secretary, will build a 3-story, 18 x 102 ft. laboratory building at Forty-second St. and Dewey Ave. Estimated cost, \$120,000. John Latenser & Sons, 626 Bee Building, architects.

#### New Jersey

**CAMDEN**—The Warren & Webster Co., Point and Pearl Sts., will build a 2-story, 43 x 71 ft., reinforced concrete, brick and steel factory, for the manufacture of heating systems and venting specialties, on north side of Pearl St., between Delaware Ave. and Point St., Ballinger & Perrot, Seventeenth and Arch Sts., Philadelphia, Pa., architects.

**NEWARK**—The Brady Brass Co., Fourteenth St., has awarded the contract for the construction of a 4-story, reinforced concrete and brick factory building, to J. Mitchell, Montgomery St. Estimated cost, \$25,000.

**IRVINGTON**—The Day-Elder Motors Co., 161 Ogden St., Newark, has awarded the contract for the construction of a brick and mill factory, on Central Ave., to H. er Construction Co., 161 Grove St., Newark.

**NEWARK**—The Mennen Gerhardt, Chemical Co., 40 Spring St., has awarded the contract for the construction of a brick addition to its plant on Central Ave., to H. M. Boremba & Co., Orange Ave. Estimated cost, \$45,000. Noted June 15.

**TRENTON**—John E. Thorp's Sons Co., Lewis St., will build a foundry and iron plant along the Delaware River, to J. E. Thorp, 1100, 000. J. Osborne Hunt, 114 North Montgomery St., architect.

#### New York

**BROOKLYN**—The Gotham Can Co., 69 Eagle St., has awarded the contract for the construction of a 3-story, 60 x 100 ft. factory, to W. R. McGarry Co., 306 Freeman St. Estimated cost, \$45,000.

**BUFFALO**—The Donner Steel Co., 475 Abbott Road, will build a reinforced concrete, brick and steel coke oven plant containing 180 ovens. Estimated cost, \$3,000,000. H. Koppers Co., Pittsburgh, Pa., engineers.

**BUFFALO**—The National Aniline & Chemical Co., Abbott Road, will build a 6-story, 150 x 250 ft., reinforced concrete, brick and steel factory addition. Estimated cost, \$300,000. H. McKaig Co., c/o owners, engineers.

**BUFFALO**—The Strong Steel Co., 33 Norris St., will build a 1-story, 80 x 300 ft., concrete, brick and steel foundry and machine shop. Estimated cost, \$75,000.

**LONG ISLAND CITY**—The Meurer Steel Barred Co., 575 Flushing Ave., has awarded the contract for the construction of a 1- and 2-story, 200 x 255 ft. factory to Peter Guthy, 926 Broadway, Brooklyn. Estimated cost, \$75,000.

**LONG ISLAND CITY**—The Rachel Asbestos Co., 609 West Twenty-second St., New York City, will build a 2-story, 90 x 115 ft., brick factory on Harris Ave. and Hancock St. Estimated cost, \$60,000. E. A. Richardson, 100 Amity St., architect.

**NIAGARA FALLS**—The Hydraulic Power Co., Hydraulic Canal, has awarded the contract for the construction of the substructure for a 3-story, 100 x 300 ft. hydroelectric plant at Canal Basin, to Dock Construction Co., 95 River St., Hoboken, N. J. Estimated cost, \$1,000,000.

**NIAGARA FALLS**—The United States Light & Heat Co., manufacturer of heating specialties, 3215 Highland Ave., will build a 1-story, 150x300 ft., reinforced concrete, brick and steel factory. Estimated cost, \$75,000. Mills, Rhines, Bellmire & Nordoff, Old Building, Toledo, O., architects.

**RED HOUSE**—A. B. Smith Co., White Building, Buffalo, will build a 2-story, 100 x 250 ft., brick chemical plant here. Estimated cost, \$35,000.

**ROCHESTER**—The Bridgeford Tool & Machine Co., Winton Ave., will build a 3-story, 60 x 200 ft. machine shop. Estimated cost, \$50,000. R. S. Byers, Chamber of Commerce Building, architect.

**ROCHESTER**—The Monroe Iron, Metal & Copperage Co., 510 State St., has awarded the contract for the construction of a 2-story, 50 x 100 ft. plant, to William Kenny, 86 Frost Ave. Estimated cost \$23,000.

**ROCHESTER**—The Vollensack Optical Co., 1415 Clinton Ave., N., will build a 2-story, 150 x 200 ft., reinforced concrete,

brick and steel optical plant. Estimated cost, \$75,000.

**SYRACUSE**—The Crucible Steel Co., 104 Madison St., has awarded the contract for the construction of a 1-story, 90 x 125 ft., concrete, brick and steel machine shop, to J. D. Taylor & Co., 115 South Salina St., Syracuse, N. Y. Estimated cost, \$40,000.

**UTICA**—The United States War Department, Washington, D. C., will build a plant on the east side of Snipe St. near the plant of the U. S. Gas & Electric Co., for the production of toluiol from gas. Estimated cost, \$65,000.

## Ohio

**CARTHAGE**—The Pollak Steel Co., Seventy-first St., Cincinnati, will build a 1-story press shop as an addition to its plant here. Estimated cost, \$8,000.

**CINCINNATI**—The Peerless Foundry Co., Eleventh and High Sts., has awarded the contract for the construction of a 1-story, 120 x 200 ft. and 60 x 120 ft. grey iron foundry, fire-proof construction, on Washington place, to J. M. Marcus Building Co., 2023 Reading Road. Estimated cost, \$75,000. Noted May 15.

**CLEVELAND**—The Cleveland Smelting & Refining Co., 357 Leader-News Building, has awarded the contract for smelting old and new metals. Estimated cost, \$200,000. E. A. Stotter, superintendent.

**CLEVELAND**—The Electrical Steel & Forge Co., Grant Ave. and Belt Line Railway, has awarded the contract for a 2-story, 100 x 200 ft. concrete, brick and steel rolling mill and warehouse. Estimated cost, \$100,000.

**ELIZABETHTOWN**—The Nitrate Division, Bureau of Ordnance, War Department, Washington, D. C., has awarded the contract for the construction of a plant for the manufacture of nitrate, to the Air Nitrate Corporation, 360 Madison Ave., New York City. Cost will run into millions.

**FINDLAY**—The Grant Motor Car Corporation, Coit and Kirley Aves., Cleveland, has awarded the contract for the construction of six factory buildings, brick and steel, to W. J. Thompson & Son Co., 6110 Euclid Ave., Cleveland. Estimated cost, \$100,000.

**FINDLAY**—The Giant Tire & Rubber Co., Western Ave., will rebuild its plant with brick and steel destroyed by fire.

**LORAIN**—The W. S. Automatic Co. will build a 2-story, 120-160 ft. addition to its plant. Estimated cost, \$100,000.

**TOLEDO**—The Nitrate Division, Bureau of Ordnance, War Department, Washington, D. C., has awarded the contract for the construction of nitrate plant No. 3, to the Air Nitrate Corporation, 360 Madison Ave., New York City. Cost will run into millions.

## Oklahoma

**DOLTHAT**—The Century Mining Co. will build a 150-ton concentration plant. Estimated cost, \$60,000.

**DOLTHAT**—The Douthat Miami Mining Co., Carden, will build a 200-ton concentration plant, requiring engines, boilers, sludge and slime tables, crushers, ore cars and bins. Estimated cost, \$60,000. Charles Douthat, superintendent.

**HOCKERVILLE**—The Bucksho Mining Co., 321 Hancock Bldg., Miami, will build a 150-ton concentration plant, requiring sludge tables, slime tables, engine and boilers. Estimated cost, \$60,000. Robert E. Brooke, superintendent.

**HOCKERVILLE**—The Lucky Jennie Mining Co. will build a concentration plant and install machinery including engines, boilers, etc. Estimated cost, \$60,000. W. F. Brooke, superintendent.

**LEADVILLE**—The Waxahachie Mining Co., Oklahoma City, will build a 150-ta concentration plant requiring sludge tables, crushers and conveyors. Estimated cost, \$60,000. J. Hare, manager.

**MIAMI**—The Aurora Mining Co., will build a concentration plant, requiring sludge and slime tables, ore crushers, motors, air compressors, belts, conveyors. Estimated cost, \$60,000. John W. Hale, superintendent.

**MIAMI**—The Indian Chief Mining Co. will build a 300-ton concentration plant. The company is in the market for sludge and slime tables, engines, boilers, engines and track cars. Estimated cost, \$75,000. John L. Sullivan, Miami, superintendent.

**MIAMI**—The Miami Mining Co., S. A. St. S. E., will build four 400-ton concentration plants. Estimated cost, \$250,000. J. P. Slaughter, superintendent. The company is in the market for sludge and slime tables, crushers, engines, boilers, air compressors and scales.

**OKLAHOMA CITY**—The Midland Motor Co. & Truck Co., 515 Mercantile Building, will build a 80 x 500 ft. factory for the manufacture of airplanes.

**PEORIA**—The Xebro Lead & Zinc Co. will build a 150-ton concentration plant, requiring slime and sludge tables, air compressors, engines, boilers, track cars, belts, conveyors and ore crushers. Estimated cost, \$60,000. R. C. Croslen, superintendent.

**PEORIA**—The Palative Lead & Zinc Mining Co., Miami, will build a 250-ton concentration plant requiring jigs, sludge and slime tables, ore crushers, etc.

**PICHEL**—The Commonwealth Zinc & Lead Co., Miami, will rebuild its mill here, destroyed by fire, and install machinery including drills, sludge and slime tables, ore cars and conveyors, crushers, belts, engines and boilers. Estimated cost, \$100,000. L. N. Dana, Joplin, Mo., superintendent.

**PICHEL**—The Miami Lead & Zinc Co., Miami, will build a 200-ton concentration plant and install machinery including hard-water sludge and slime tables and lumber for mill. Estimated cost, \$65,000.

**POTEAU**—The Poteau Window & Dry Plate Glass Co. will construct four buildings for the manufacture of glass for windows and photographic dry plates.

## Pennsylvania

**CONNELLSVILLE** — The McCairns Foundry Co. has awarded the contract for the construction of 60 x 65 ft. concrete and steel addition to its plant on the west side, to Cooper Patterson. Estimated cost, \$15,000.

**MIDLAND**—The Pittsburgh Crucible Steel Co., Empire Building, Pittsburgh, will build a mill here. W. G. O'Malley, manager.

**PHILADELPHIA**—The Barrett Manufacturing Co., Margaret and Bermuda Sts., has awarded the contract for the construction of a 1-story, 60 x 65 ft. concrete, brick and steel addition to its factory for the manufacture of coal tar products, to A. Raymond Raff Co., 1635 West Thompson St. Estimated cost, \$15,000.

**PHILADELPHIA**—The Gosa-Brockman Co., 12 North Fifth St., has awarded the contract for the construction of a 1-story, 60 x 62 brick and steel machine shop on Chestnut St. Estimated cost, \$15,000.

**PHILADELPHIA** — The Nitrogenous Chemical Co., 101 West End Trust Building, has awarded the contract for the construction of a 2-story, concrete and brick factory addition at Thirty-seventh and Tasker Sts. to Ernest Roth, 1541 Cabot St. Estimated cost, \$50,000.

**PHILADELPHIA**—The Super Glass Co., 3400 Disston St., will build a 1-story, 25 x 25 ft. brick factory addition at Howell St. and State Road.

**RUTHERFORD**—The Reading Railway Co., Atlantic and Arkansas Sts., Reading, has awarded the contract for the construction of a 1-story, 50 x 175 ft., brick machine shop here, to A. Woolfel, Lancaster. Estimated cost, \$50,000.

## Tennessee

**NASHVILLE**—The Southern Machine & Foundry Co., 213 Fourth St., S., will rebuild its plant lately destroyed by fire.

## Texas

**SAN ANGELO**—The Great Republic Tire & Rubber Co. will build a factory here. Estimated cost, \$100,000.

**WACO**—The Boone Tire & Rubber Co., c/o Chamber of Commerce, will build a factory for the manufacture of automobile tires and other rubber products. Roy E. Lane, Waco, architect.

**WICHITA FALLS**—Sunshine State Oil Co. has awarded the contract for the construction of an oil refinery, to the United Iron Works, Mill and Prospect Sts., Springfield, Mo. Estimated cost, \$150,000.

## Washington

**SEATTLE**—The Gulowen-Grel Engine Co., Alaska Building, has awarded the contract for the construction of a 2-story, 174 x 300 ft. factory on Salmon Bay Dock, to consist of a 174 x 300 ft. machinery and office building, 94 x 132 ft. foundry and 30 x 90 ft. pattern shop to M. Arson, Downs Block. Estimated cost, \$126,500.

## West Virginia

**MOUNDSVILLE**—The United States Smelting Corporation, Prisco Building, Joplin, Mo., will build a plant for smelting ore here. Estimated cost, \$1,000,000. C. E. Marshall, Joplin, manager.

## Wisconsin

**MILWAUKEE**—The National Brake & Electric Co., Bellevue and Cambridge Sts., will build a 1-story, 40 x 130 ft., concrete and brick factory. Estimated cost, \$22,000. Noted June 15.

**MILWAUKEE**—The Cutler-Hammer Co., St. Paul Ave., west of Thirteenth St., will build a plant. Estimated cost, \$6,000.

**MILWAUKEE** — The Globe Seamless Steel Tube Co., Colby-Abbot Building, will build a 1-story, 130 x 170 and 130 x 250 ft. brick and steel plant.

**SHAWANEE**—The Wolfe River Paper & Fiber Co. will build a 2-story, 165 x 50 V. addition to its mill. Estimated cost, \$5,000. L. A. DeGuere, Grand Rapids, engineer.

**SHEBOYGAN**—The Jenkins Machine Co., 315 North Eighth St., will build an addition to its plant. The company recently obtained a large war order.

**WEST ALLIS**—The Universal Machinery Co., 785 Thirtieth St., Milwaukee, will build a 1-story, 150 x 480 ft. machine shop here. F. E. Gray and Val A. Siebert, 86 Michigan St., Milwaukee, architects.

## British Columbia

**BEAVER COVE**—The Beaver Cove Lumber & Pulp Co., London Building, Vancouver, will build lumber and pulp mills here. Estimated cost, \$250,000. W. H. White, manager.

**VANCOUVER** — The Department of Mines, Dominion Government, Ottawa, Ont., will build ore testing plant. Estimated cost, \$60,000.

## Manitoba

**WINNIPEG**—The Hygiene Products, Ltd., 607 Young St., will build a plant here.

## Nova Scotia

**HALIFAX**—Robinson Co., Ltd., has awarded the contract for the construction of a brick and reinforced concrete garage and repair shop, to Maritime Construction Co., Queens Building. Estimated cost, \$50,000.

**STELLARTON**—W. P. McNeil will build a munition plant here. Estimated cost, \$60,000.

**SYDNEY**—The Dominion Iron & Steel Corporation, 112 St. James St., Montreal, Que., will build a steel rolling mill. Estimated cost, \$50,000.

## Ontario

**BRAMPTON**—The Hercules Rubber Co. will build a plant for the manufacture of automobile tires, etc. Estimated cost, \$60,000. Thomas Thauburn is interested.

**TORONTO**—The Gutta Percha Rubber Co., Ltd., 4 Yonge St., will build a factory on O'Hara Ave.

**TORONTO**—The National Iron Works, Ltd., foot of Cherry St., will build a 1-story, steel and galvanized iron addition to its factory. Estimated cost, \$15,000.

**TORONTO**—The Universal Tool Steel Co., 153 Dufferin St., will build a 1-story, brick addition to its machine construction plant. Estimated cost, \$45,000. G. C. Briggs, 27 Wellington St., E., architect.

**WILLAND**—The Metals Chemical Co. has awarded the contract for the construction of a plant for the manufacture of gunpowder to the Burns Cement-Gun Construction Co., Toronto.

**WINDSOR**—The Driver Harris Co., Harrison, N. J., has purchased a site here and will build a plant for the manufacture of all kinds of alloys. Estimated cost, \$60,000.

## Quebec

**COTE ST. PAUL**—The Crane Co., Ltd., Montreal, will build a plant for the manufacture of valves, fillings and a full line of plumbers' supplies, on St. Patrick St. Estimated cost, \$400,000. R. T. Crane, Jr., president.

**MONTREAL**—P. Lyall & Sons Construction Co., Ltd., 701 Transportation Building, will build a 1-story, brick forge shop, on Notre Dame St., E. Estimated cost, \$10,000.

**TRIMSKAMING**—The Riondon Pulp & Paper Co., 165 Beaver Hall Square, Montreal, will build a sulphite mill and power house here.

## Industrial Notes

**THE WILPUTTE COKE OVEN CORPORATION** announces the removal of its offices and engineering department to the Winfield Building, No. 469 Fifth Avenue, corner of 40th Street, New York.

**THE BOOTH-HALL COMPANY**, 565 West Washington Boulevard, Chicago, Ill., has made arrangements with the Bradford-Ackerman Corporation, 30 East 42d Street, New York, to take entire charge of sales in the eastern section of the United States.

**THE WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY**, Pittsburgh, Pa., has purchased the property, business and good will of the Krantz Manufacturing Company, Inc., Brooklyn, N. Y., manufacturers of safety and semi-safety electrical and other devices, such as auto-lock switches, distribution panels, switchboards, floor boxes, bushings, etc. The Supply Department of the Westinghouse Electric & Manufacturing Company will act as exclusive sales agent for the products of the Krantz Manufacturing Company, whose business will be continued under its present name. Mr. H. C. Hoke, of the Westinghouse Electric & Manufacturing Company, will represent the Supply Department at the Krantz Factory.

**HAMILTON & HANSELL**, Inc., New York, have recently contracted with the Government for two Rennefelt electric furnaces which will be installed at the United States Mint in Philadelphia, for melting bronze and cupro-nickel for coins. These furnaces are of the latest design, equipped with overlap tilting and automatic side electrode feeding mechanism. The 1000-lb. Rennefelt furnaces with its electrical equipment installed some time ago, is to be shipped to the Pacific coast and installed at the Mint in San Francisco.

**THE ALGOMA STEEL CORPORATION**, of Sault Ste. Marie, Ontario, is going to enlarge its by-product coke oven plant and a contract for an additional battery of twenty-five Wilputte ovens has just been let to the Wilputte Coke Oven Corporation, of New York City, making fifty new ovens now in process of construction. The two new batteries will probably be ready for operation this year.

**THE R. U. V. COMPANY, INC.**, announce that they have moved their New York office to 130 Broadway.

**THE WHEELER CONDENSER & ENGINEERING CO.**, Carteret, N. J., has under agreement with the Sugar Apparatus Manufacturing Co., acquired the exclusive right to manufacture and sell evaporating apparatus under the patents of the late John Lillie, president of that company. The advice of Mr. Lillie is to be at all times at the command of the Wheeler Condenser & Engineering Co. and at the same time Mr. Lillie will give cooperation of the entire engineering, sales shop and erecting organization of the Wheeler Company.

**THE ZAREBSKA COMPANY** announce the removal of the offices to Niagara Life Insurance Building, Room 1506, corner Franklin and Mohawk Streets, Buffalo, N. Y.

**THE MEXICAN PROMOTING AND INVESTING CORPORATION** have moved their New York office to 52 Broadway, Room 622.

**THE ELECTRON CHEMICAL COMPANY** are now located in Room 1403, 347 Madison Avenue, New York.

**PAPE TERMINALS CO.**, Wilfred N. Ball, Engineer, 225 First National Bank, Oakland, Calif., wants catalogs and other data from manufacturers of materials or equipment used in the construction of piers, warehouses, industrial buildings, b-h line, railway and street work and cargo handling equipment, coal bunkering and handling equipment, floating dry docks, marine railway equipment and general ship yard machinery and equipment.

**Government Contracts Awarded**—Contracts recently awarded by Ordnance Department of U. S. Army:

**Winkler & Evans (Inc.),** New York City, N. Y.

**MR. C. H. VOM BAUR** has been elected vice-president of the T. W. Price Engineering Company. He has designed, operated and installed over thirty electric furnaces in this country, and is joint author of the book on "Electric Furnaces in the Iron and Steel Industry." This company has designed and installed new plants for the Lumm Steel Co., Watervliet, N. Y.; Hamm Steel Co., Syracuse, N. Y.; Century Steel Co., Poughkeepsie, N. Y.; Ulster Iron Works, Dover, N. J.; Hubbard Steel Foundry Co., East Chicago, Ind., and numerous others. The offices of the company are in the Woolworth Building, New York City, and 14 East Jackson Boulevard, Chicago, Illinois.

**THE RAINEY-WOOD COKE CO.** has been organized by the W. J. Rainey interests, operating coal mines and coke works in the Connellsville region, and the Alan Wood, Iron & Steel Co., with blast furnaces and steel works at Swedeland, Pa., for the purpose of constructing a large by-product coke plant of 330 ovens at Swedeland, Pa. The coal for this plant will be furnished by W. J. Rainey from their mines in the Connellsville region. Work has been started on the first unit of 110 of these ovens, and it is expected to have the plant in operation within fourteen months. This first installation will supply coke, gas and tar to the Alan Wood, Iron & Steel Co. and will have sufficient additional capacity to furnish foundry coke for the Eastern market. A complete by-product recovery plant will also be constructed for the purpose of recovering sulphate of ammonia and toluol to the U. S. Government. It is proposed to install the remaining units at the earliest possible date, in order to insure a continuing supply for the independent blast furnaces in the Schuylkill and Lehigh Valleys.

**THE INDEPENDENT FILTER PRESS CO., INC.**, has removed from 47 West 34th Street, New York, to 418 Third Avenue, Brooklyn, N. Y. The factories and office are now under one roof and the manufacturing is to be done under the supervision of Mr. A. C. Cuttler. Double the amount of machinery has been added in order to give prompt and quick deliveries.

## New Publications

**NEW BUREAU OF MINES PUBLICATIONS:**

Bulletin 110, Concentration Experiments on the Siliceous Red Hematites of the Birmingham District, Ala. By J. T. Singewald, Jr.; Bulletin 132, Siliceous Dust in Relation to Pulmonary Disease Among Miners in the United States. By J. T. Singewald, Jr. and K. Lanza, P. B. Laney and G. S. Rice; Bulletin 146, Technology of Salt Making in the United States. By W. C. Phalen; Technical Paper 118, The Interrelation of Moisture in Coke. By A. C. Fieldner and W. A. Selvig; Technical Paper 182, Plotation of Chalcopyrite-Pyrrhotite Ores of Southern Arizona. By W. H. Coghill; Technical Paper 183, New Views of the Combustion of the Volatile Matter in Coal. By S. H. Katz; Technical Paper 201, Accidents in Metallurgical Works in the United States During the Calendar Year 1916. By Albert H. Fay; Bulletin 151, Recovery of Gasoline from Natural Gas by Compression and Rectification. By W. P. Dykema; Technical Paper 185, Use of the Interferometer in Gas Analysis. By Frank M. Seibert and Walter C. Harpster; Technical Paper 202, Metal-Mine Accidents

in the United States during the Calendar year 1916. Compiled by Albert H. Fay; Bulletin 149, Bibliography of Petroleum and Allied Substances, 1915. By E. H. Burroughs.

**NEW BUREAU OF STANDARDS PUBLICATIONS:** No. 321, Thermal Expansion of Alpha and Beta Brass Between 0 and 600 deg. C., in Relation to the Mechanical Properties of Heterogeneous Brasses of the Muntz Metal Type. By P. D. Merica and L. W. Schrad, issued May 4, 1918; No. 104, Effect of the Size of Grain in Fire-Clay Bodies. By F. A. Kirkpatrick, issued March 12, 1918.

**CIRCULAR LETTER VIII-4**, giving a working bibliography of reference and handbooks on the properties of metals and alloys. This circular has been prepared in answer to numerous requests for general and comprehensive information and can only be answered with the statement of the sources where such information can be obtained.

**TANNING MATERIALS OF LATIN AMERICA.** By Thomas H. Norton. Copies of the report can be obtained from the Superintendent of Documents, Washington, D. C., or to any of the District Offices of the Bureau of Foreign and Domestic Commerce.

**AN INDUSTRIAL SURVEY OF SEATTLE.** By Curtis C. Aller. Bulletin No. 3, issued by the University of Washington, Bureau of Industrial Research, Seattle, Wash.

**FUEL ECONOMY IN THE OPERATION OF HARBOR-REAR STEAMERS.** Circular No. 1, published by the University of Illinois, Urbana, Ill. Price \$0.20.

**MINING ENGINEERING AS A PROFESSION.** A publication of the University of Arizona, College of Mines and Engineering, Tucson, Arizona.

**THE HARRISON WORKS**, paint and chemical manufacturers owned and controlled by E. I. du Pont de Nemours & Company of Wilmington, Delaware, have just issued six booklets as follows: "Harrison Blue Ribbon Chemicals," "Harrison Oil Paint," "Harrison Oil Stains," "Harrison Automobile and Carriage Paint," "Harrison Porch Chair Enamel" and "Shingle Homes." Copies may be had upon request.

**EMERGENCY WAR TRAINING FOR AIRPLANE MECHANICS.** Bulletin No. 12, issued April 1918, by the Federal Board of Vocational Education, Washington, D. C.

**"MANUFACTURING OPPORTUNITIES IN THE STATE OF WASHINGTON"** has just been issued by the State Bureau of Statistics and Immigration, State of Washington, Olympia. Copies may be had upon application.

**THE UNIVERSITY OF IDAHO**, Moscow, Idaho: Vol. XIII, No. 1, which is the annual catalog for 1917-1918 issued May, 1918, with announcements for 1918-1919.

## Manufacturers' Catalogs

**P. H. & F. M. ROOTS COMPANY**, Connersville, Ind.: Catalog 63 illustrating and describing rotary gas exhausters for foul gas pumping service, corrosive gas handling with high-pressure booster service and special devices.

**J. P. DEVINE COMPANY**, Buffalo, N. Y.: Bulletin No. 105A, which describes and illustrates apparatus for the color, chemical, dyestuff and allied industries. Copies of this bulletin can be had by applying to the above company.

**BUFFALO FORGE COMPANY**, Buffalo, N. Y.: Section No. 108, March, 1918, covering stationary forges.

**COMPUTER MFG. CO.**, 25 California St., San Francisco, Calif. A booklet on the Ross precision computer which is said to be equivalent to a slide-rule 100 feet long.

**THE BRAUN CORPORATION**, Los Angeles, Calif.: Catalog No. 50 on the Braun laboratory appliances, describing and illustrating the many different types.

**THE BROWN INSTRUMENT COMPANY**, Philadelphia, Pa., has just issued an interesting chart printed in four colors showing the melting points of chemical elements, together with a heat-color scale giving a useful conversion table of Fahrenheit and Centigrade degrees. The color-scale includes 50 elements from nitrogen to carbon, and should be found valuable in all kinds of heat treating work.

**THE COLORADO FUEL & IRON COMPANY**, Denver, Colorado: Industrial Bulletin, Vol. III, No. 3, April 30, 1918, which contains articles of timely interest for the information of their employees.

### Economics of Prices and Production in War Time

PROBABLY every engineer has, at some point in his education, gained at least a smattering of the science of economics. If his experience coincides with ours, his study of the subject was rather superficial, due to pressure of other work deemed more important, and his recollection of it is confined to a few hazy notions on the law of supply and demand. As a logical consequence he is likely to be a bit confused when the subjects of price-fixing and *laissez faire* are expounded by their proponents as cures for the economic evils that beset us in war times.

It is with a view to clarifying the situation somewhat that we have asked Professor McCrea of Columbia University to write a brief exposition of the economics of prices and production in war times. His article appears elsewhere in this issue, and we believe engineers generally can afford the time necessary for its study, and that they will feel repaid for the effort. Professor McCrea has picked illustrations and phases of the subject appropriate to the engineering profession.

### Buying a Scientific Pig in a Poke

IT IS doubtful if any organization other than Congress could have been induced to heed the representations of a comparatively unknown scientist on the mere claim that he had a mysterious and wonderful machine for the development of energy. Congress does some things well, but when it dabbles in science and engineering it is likely to make a poor showing.

For some time now we have been awaiting the revelations promised by Garabed T. K. Giragossian as a result of official encouragement granted him for the development of whatever it was he had in mind when he induced Congress to back him. The report of the investigation committee, composed of four Massachusetts Institute of Technology scientists and a fifth engineer, is brief and negative. It is about what all engineers anticipated, certifying that the model was not in shape to run or develop power; also that "the inventor admitted that he had no working machine and that he was merely explaining principles." Apparently the "principles" did not satisfy the committee, because they are dismissed as unsound, and the device is discredited as inoperative. In short, the bubble burst when exposed to mere inspection.

The inventor is reported to be undismayed, and still determined to demonstrate his idea and force its acceptance by an unwilling and ungrateful government. The sooner the incident is dismissed and forgotten, the

less likely it is that other inventors of perpetual motion machines will seek the ear of Congress and implore official recognition. We hope the time will come when sound engineers can get as much recognition on their merits, as fanciful dreamers secure through persuasive powers of speech and glittering promises.

### Administering Alien Property

**I**N taking over the vast amount of enemy alien property by the United States Custodian we have been very favorably impressed with the high class of men who have been appointed as administrators. The majority of names, which at first glance are familiar to us, are those of gentlemen who have successfully administered estates of immense value either as owners, trustees or corporation officers. We do not observe, however—and we say this subject to correction for not having the complete list before us—names of men having the technical training to understand the nature of the business which they have in hand, in chemical manufacture.

Now, chemical industry does not accord with the convention which became established in the joyous old days, to the effect that given a factory with machinery, a lot of workmen and a superintendent, it was bound to succeed if only the members of the board of directors were all successful men. It doesn't work that way at all. A banker, a broker, a street railway magnate, a dry goods merchant and a lumber king, no matter how rich they may be, are not the right persons to make chemical products or to sell them. Their time is worth too much to waste it in doing nothing, and the mere formality of attending board meetings without understanding what is going on, is waste. It is chiefly in German-owned works that many enemy aliens are employed as managers and superintendents as well as technicians. Therefore we hold that at least one member of each board of directors of every German-owned chemical works should be an American chemist of high standing. Otherwise, no matter how competent the board is, the insiders may put something over on the directors that will only be discovered after it is too late.

Enemy property should be conserved, and properly conserved, because as a people we still remain civilized, and if we hold our heads high and keep up our faith, German depravity will not spread its infection among us. But as to the wisdom of the appointment of men of technical training to these boards, we think it important, and we urge it upon the Custodian of Alien Property. There are many reasons why it should be done, and we know of none to the contrary.

### What Does the Employer Expect of the College-Trained Chemist?

**W**ITH the purpose of gaining the point of view of the manufacturer regarding the qualifications which lead the college-trained chemist to a successful career and rapid promotion, the *Kansas Chemallurgist* sent out enquiries, some of the replies to which are printed in the May issue. The general consensus of opinion was that personal characteristics were equally as essential for stepping to the front of the ranks of the chemical profession as pure scientific knowledge and training. Such qualifications as honesty, initiative,

imagination, enthusiasm, persistence, aggressiveness, tact, loyalty and progressiveness were cited with emphasis. One writer thought these qualities should not be regarded as gifts, but as the acquirements of a properly directed mind which became natural, just as any physical habit does, by practice.

Dr. W. R. Whitney of the General Electric Co. may well be quoted: "We expect of each man at the start certain definite things, but when he does only what we expect from him, he does not get along as rapidly or as well as when he exceeds our expectations, and that is the kind of man to train, if possible. For example, a man trained as an analytical chemist may be added to the force. It is satisfactory if he is and remains a fair analytical chemist, but it almost always happens that opportunities come to him for extensive or special work. It may be no more than extensive development of the appreciation of the uses of analytical chemistry in our field. Or it may be that, because of his particular interest or enthusiasm, he develops into an expert in some line, such as electric-furnace products, tool-steel manufacture, etc. The actual manipulation necessary for the chemist in the analytical field as applied to our own experience is not difficult enough or rare enough to warrant high salaries, except where it is combined with what may be called interpreting powers. An analytical chemist who actually performs all the analyses needed in a running laboratory, but does nothing else, can seldom be paid a decent salary, because there are so many of them."

Without doubt, the chemist who gets the coöperation of his associates and has the power of uniting his forces in their best formation for attacking his work is just as much of a leader as any of our executives, civil or military. To do this, he must have character, the more important attributes of which have been mentioned. The employer seeks the man that can promote the welfare of the firm and be promoted himself in return. To do this, he must have the correct point of view and the will to execute his conceptions. Then he will always produce the desired results.

### Post-War Problems in the Chemical Industry

**I**N RECENT issues of *CHEMICAL AND METALLURGICAL ENGINEERING* we have been directing attention through a series of articles by our Washington representative to the imperative necessity of beginning at once to plan for the reconstruction of our industries after the war. The inevitable readjustment that will be necessary when peace comes should be anticipated by the best minds in the industry so that the change will be made with as little dislocation as possible.

It must be evident to all that our chemical industry, being basic in the production of munitions of war, has undergone tremendous expansion. Production far exceeds anything known or needed before the war, and the troublesome question arises, What are we going to do with our production when the abnormal demands of war no longer exist? The answer will not be so difficult in the case of those chemical products which are new to this country and which will supplant former importations; but in the case of acids and alkalies, chlorine, ferro-alloys, air-nitrates and some other products in

which we have had a tremendous expansion there will be need of careful and constructive thought. The use of these materials must be extended in proportion as their production has expanded or there will be economic loss and waste.

Great Britain already has approached the problem of sulphuric acid overproduction, and the makers have been in conference on the advisability of forming a National Sulphuric Acid Association. Recommendations have been made looking toward the use of excess acid in the manufacture of fertilizer and the more extended use of that material. Vitally and intimately related to this program are the subjects of cheap transportation, education of the farmer, equitable taxation and a scheme for the scrapping of useless plants. The cooperation and support of the Government is sought and expected.

In our own country we have such agencies as the Chemical Alliance and the American Chemical Society which should take the initial steps toward protecting our chemical industry when peace comes. Both organizations are directed by leaders in the industry, and are favorably situated to sense its post-war problems. Investigations should be started at once, preferably by men whose minds are free from concern with the problems of present production. A symposium on the subject at the Fall meeting of the American Chemical Society should be of inestimable value if properly organized.

### Profits and Profiteering

THE Federal Trade Commission's report on "profiteering" was made public June 29 and immediately there arose a storm of criticism in many branches of the trade press. Perhaps if the Commission were afforded an opportunity to comment upon the editorials that have been written about its report it would find as much occasion to criticise the editorials as the editors found to criticise the report. It could take advantage of the editors in one respect, by giving the editorials the careful reading it is evident some of the editors did not give the report.

The report has been dubbed "extraordinary," for instance, but that is not particularly remarkable in a report on a practice that is so extraordinary that its very name has not hitherto been recognized by the lexicographers. It is suggested also that the report reminds one of the "muckraking" days. A careful reading of the report, however, from the viewpoint of the circumstances which moved the Senate to call for it, does not indicate that it is such a remarkable document after all. The chain of circumstances that led to it was short and closely linked. On May 27 the President appeared before Congress and asked that the session be prolonged to consider the taxation program for the calendar year 1918, four billions having been the estimate for the taxes levied against 1917, while the amount would have to be increased greatly. The President said:

"There is abundant fuel for the light in the records of the Treasury with regard to profits of every sort. The profiteering that can not be got at by the restraints of conscience and love of country can be got at by taxation. There is such profiteering now and the information with regard to it is available and indisputable."

The Senate accordingly called upon the Federal Trade Commission for a report giving such information as the

Commission had available as to how profiteering could be got at either by taxation or by enactment of more effective criminal statutes. The Commission in its report, however, does not propose any additional criminal statutes, but rather reports that there are cases of men violating existing law, and that "The Federal Trade Commission has been vigilant and untiring in its exclusion of these practices." It does point out that there are large profits, and that is precisely what Congress desired to find. That is not a hallucination on the part of the Commission, not even a new discovery. When price-fixing was being discussed, about a year ago, it was the common contention of producers that the most efficient method of procedure for the Government would be to allow large profits, and then tax those profits as far as necessary. Perhaps it was poor advice, but at any rate it has never been formally withdrawn.

The Commission deserves much credit for bringing out strongly a very practical and important fact in connection with profits and production, and that is that in a given industry there are likely to be large profits and small profits, from which the Senate will experience no difficulty in deducing that the efficient thing is to tax profits on a graduated scale rather than reduce prices until the profits of the more efficient producers become normal and the profits of the less efficient are converted into losses causing them to cease production.

Criticism of the Federal Trade Commission's report, rather a tame document on the whole, but marked by some lurid language which is not illuminating and had much better have been omitted, apparently loses sight of the fact that the Commission has had an important part in the fixing of prices, being constantly consulted by the War Industries Board and the President. If it desired any general scaling down in prices its representations would have been made in those quarters and would not have been held back for presentation to the legislative body when the latter is seeking profits upon which to levy taxes.

On the whole, the report clears the situation somewhat, though to no great extent. It is more important in what it does not say than in what it does say, except as to the one point that it emphasizes the fact that profits vary greatly among the different producers in an industry. Congress can now forget about "profiteering," for which there is no precise definition, and address itself to the taxing of "excess profits" or "war profits" which can be defined precisely, in dollars and cents, in various ways. The law taxing 1917 profits defined the excess by a scale of percentages based on capital investment. The original House bill had taken the average profits of 1911-12-13 as a basis. Lately the British system has been proposed, based on the two best of those three years. The President told Congress that the present tax laws "are marred, moreover, by inequities which ought to be remedied," and yet it appears the taxes were computed and paid without a great deal of difficulty. It has always been a debatable question how much capital the United States Steel Corporation has invested, yet although the tax is based on capital investment it appears that the Corporation paid precisely the tax it computed before the time had arrived for it to make its taxation report to the Treasury Department. The prospects are that a suitable tax law will eventually be enacted.

## Readers' Views and Comments

### Molecular Physics of Ore Flotation

*To the Editor of Chemical & Metallurgical Engineering*

SIR:—I would like to correct a misstatement by Coghill and Anderson in their recent article entitled "On the Molecular Physics of Ore Flotation."

This statement is as follows:

Other writers have made similar attempts (calculation of capacities) by using principles incorrectly. The most striking case is that of Van Arsdaale. He begins with the promise that "the maximum weight that can be supported on the surface of water is equal to the surface tension of the area supporting the weight." Beginning thus with a false premise naturally he ends with false conclusions. It is scarcely hypercritical to say that for these fallacies to go unchallenged, after receiving favorable editorial comment and being incorporated in a book, portends a tardy science of flotation.

The portion of my article referred to read as follows:

We can then ask the question, How and why does a particle heavier than water float on a water surface? and if we can answer this we can expect considerable light on the whole subject. It is obvious enough that if a needle or anything else specifically heavier than water floats it does so primarily because of the effect of surface tension.

Now if this is true, there should be a relation between surface tension factors and the maximum weight that we can support on a water surface, and if we can experimentally verify such a relation we can consider our assumption proved.

It has been stated that the maximum weight that can be supported on a surface of water is equal to the surface tension of the area supporting the weight: that is to say that one square centimeter will support about eighty-one milligrams. As a matter of fact it can easily be shown that a square centimeter of water will support much more than this weight. We can however derive the relation we are after from the surface tension formulas for the difference in pressure between two sides of a curved surface. By the use of these formulas we can calculate the maximum size of cylinder that will float, and can verify our hypothesis experimentally by floating, for example, clean copper wires of various sizes. The maximum size of copper wire, when calculated thus, is about seventeen or eighteen B. & S. gage, depending on the area of contact. By careful manipulation we can float a wire of a size very close to that calculated, and can therefore be sure that our hypothesis is correct.

At the time my article appeared there were several flotation "theories" and the object of my argument was to show that flotation was due primarily to surface tension. This may seem superfluous now in view of our increased knowledge of the subject, but at that time flotation was popularly a "mystery."

It is, I think, obvious from my article as quoted above that I do not use the statement quoted by Coghill and Anderson as a premise at all but do prove that the statement is wrong, and that a close approximation to the maximum weight of a particle of either spherical or cylindrical shape that can be floated can be calculated by the use of the formulas given. A correction was later made of a transposed formula, but the conclusion I think remains correct.

It was distinctly stated in the article that details were not gone into and the figure given therefore of about seventeen gage copper wire as the largest size capable of flotation was only approximate, and furthermore as stated the size depends on assumptions made as to the amount of wet surface. The object of the

argument was not to determine an exact size of particle but to prove that surface tension was the primary cause of flotation, and not more or less obscure "electrostatics." The agreement between the calculated figure and that experimentally obtained while possibly not so exact as that obtainable by more elaborate methods was sufficiently so for the stated purposes of the argument.

In any case I think it will be clear from the above that the authors of the present paper were not warranted in making the statement that I used as premise the obviously incorrect statement given, but on the contrary this is distinctly given as a quotation and is proved to be wrong.

G. D. VAN ARSDALE.

Douglas, Ariz.

### The Recent Flotation Decision

*To the Editor of Chemical & Metallurgical Engineering*

SIR—It appears that the U. S. Circuit Court in California has overruled the District Court in Montana, and concluded that the Supreme Court did not mean 1 per cent of oil or fractions thereof, but  $\frac{1}{2}$  per cent of oil and less.

The California Court in substance decides that extra-neous oil added for no purpose other than to avoid infringement may be classed as process oil and considered as oil desirable or useful in flotation results. The issue is forgotten, or not understood, that the essential oil in kind and degree, as described in the flotation patents at issue, is used to obtain the results, and that the extra-neous oil is a neutral non-essential grade, not improving results but rather hindering them.

If it were shown by defendants that there was advance in the art, or a new process discovered by the use of oil, in any way, in excess of 1 per cent or even in excess of a fraction of 1 per cent, then the ruling of the California Court would be understandable. As it is, there appears no reason to doubt that the Supreme Court will again rebuke the California decision and stand on the broad ground it has taken, that the patents of Messrs. Sulman, Picard and Ballot are valid and must be broadly sustained.

If new evidence is shown, not now known to the profession, there is of course a chance to nullify the invention of Messrs. Sulman, Picard and Ballot as anticipated by prior art. If invention can be shown by advances in the art as described and practised under patents of Messrs. Sulman, Picard and Ballot, then a new flotation invention exists that may have individual standing.

I was called upon to give opinion in this issue prior to the Supreme Court decision, and I maintained that the Delaware Court must be sustained by the Supreme Court as it was. When the issue was started afresh regarding the use of excess oil to avoid royalty payments, I maintained that the Court must decide that the process of Messrs. Sulman, Picard and Ballot was still being used, no matter what excess of foreign matters like neutral oil existed, unless a new flotation process could be shown, with results that were not obtained solely by the use of the minor fraction of suitable oil

and the proper degree of agitation, as called for by patents mentioned. The Montana courts did so find, and I trust I may be permitted to again express opinion, for the issue to my mind has always been very clear.

There appears a lot of camouflaging and irrelevant matter in opinions expressed that, like the California decisions, show the minds do not grasp the real issue. The fact is that a commercial advance was created by the process of Messrs. Sulman, Picard and Ballot and was at once grasped by industry with immense profit. We may also say that unfortunately the patents were exploited for gain rather than administered by the inventors or a research board, but while this fact may excite opposition and litigation, it cannot change the legal status. Custom has devised no other form of meeting the money power of industry.

The Supreme Court recognized invention, saw the large benefit to community interests, the object of our patent laws, and saw that the process was one of degree and hard to define. In using the 1 per cent of oil definition of degree, the Supreme Court sustained the reading of the claims as a liberal interpretation, and it will be found that the use of much more than 1 per cent of oil will not break the patent protection, unless some new process or result is obtained thereby, and the burden of proof will be upon the inventors of this new process to prove it, which has not been presented.

It seems to me that the opinions and editorials I read are discussing words rather than issues and I can see no purpose in discussing the per cent of oil without the results and purpose of that oil, and as to the use of the term "critical" I feel that it was a fair term to use, when used in the light of the kind of oil and condition of agitation. It will be ruled that the per cent of oil has little bearing on the issue so long as the active oil that does the work is a fraction of a per cent which has been true up to the present.

The Supreme Court must protect invention that is the basis of community advance, and thus patent law; and in order to avoid royalties to owners of the Sulman, Picard and Ballot patents industry must show that results are not obtained by the critical conditions demonstrated by those patents. If Messrs. Sulman, Picard and Ballot were not the first to demonstrate, then the patents may be vacated, but on no other grounds.

## The Microscope in Ore-Dressing

To the Editor of *Chemical & Metallurgical Engineering*

SIR:—Having read with interest the article, "Approximate Determination of the Minerals in Concentrates by Means of the Microscope," by Kirby Thomas and Frederick W. Apgar, I am enclosing a brief outline of the use of the microscope in the Missouri School of Mines Laboratories. This outline was written some years ago so does not mention the article above noted.

This outline under methods No. 1, 2 and 4, shows three uses which Messrs. Thomas and Apgar do not consider. In method 2 the microscope had been found very helpful as the disappearance of the middling can be readily noted and the most economical size for crushing can be determined. In performing some experiments on the flotation of copper carbonates after

sulphide-filming I have found the microscope especially valuable for noting the efficiency of various filming methods. Material that is sized between close limits lends itself more readily to a microscopic examination than unsized material. Very often a slight panning in a watch glass will aid. Material through 260-mesh can readily be examined if the fines are removed by panning.

Numerous articles have appeared from time to time on the use of the microscope in petrography, metallography and qualitative chemistry, but no mention has been made of its use in ore-dressing.

The microscope can be used to advantage for at least four purposes, namely:

1. The determination of the mineral constituency of an ore that has been crushed.
  2. In conjunction with a set of standard sieves for the determination of the critical diameter of an ore (the diameter of grain that shows all free mineral, no middling).
  3. In obtaining an approximate analysis of the products of various concentrating machines.
  4. Measuring the size opening in screens.
- In explaining the above uses the subject will be discussed under the following heads:
- a. Instrument used.
  - b. Source of light.
  - c. Magnification.
  - d. Methods of making determinations.

a. *Instrument Used.* The instrument used is the Bausch and Lomb metallurgical microscope with mechanical stage. Any instrument could be used, but there is a decided advantage in using the mechanical stage having lateral movement in two directions as well as vertical movement. The binocular microscope is good for comparing specimens.

b. *Source of Light.* Good sunlight has an advantage over artificial light and is best reflected upon the material from above, as light from below does not give good illumination. If the day is dark, it is best to use artificial light. The strength of light needed is determined by the magnification used. A plain 60-watt lamp is best for low magnification; a Nernst or Leitz lamp with bull's-eye condenser for high magnification.

c. *Magnification.* Low magnification from about 20 to 80 diameters serves best for general purposes. In studying products from fine screens and fine products in general, higher magnification is better. A little practice in this work soon determines what combination of lenses it is best to use.

### d. Methods:

1. *Mineralogical Analysis.* For this work the ore is panned and dried; both products are put on small watch-glasses, placed under the microscope and the light adjusted. It is very easy for one with a knowledge of mineralogy to distinguish minerals, at least the more common ones as galena, blende, quartz, calcite, etc. With a little work one could be able to distinguish a larger variety. The knowledge of the ore gained by this analysis will aid more in working out various mill processes than will any qualitative chemical analysis or mineralogical analysis of the lump ore.

2. *Critical Size.* In this determination the procedure is more tedious, as a screen analysis followed by a

thorough microscopic analysis is required. The operation is as follows: After making the screen analysis take the product from each screen, mix intimately, place on a small glass slide under the microscope and make all adjustments. By careful examination the mesh at which all the particles of valuable mineral are set free from gangue and from each other can be determined, and, by counting, one can determine the ratio of these particles on each screen.

3. *Approximate Analysis.* Take a sample of the various products such as head, concentrate, middling, or tailing while the machine is working, place on a watch-glass and examine while wet for a hurried result, or dry on a hot-bath for a more careful study. In a very few minutes one can note exactly what work a machine is doing by noting the ratio of gangue particles to particles of valuable minerals.

4. *Measuring Screens.* By placing the screen to be measured under the microscope and using a calibrated Filar micrometer one can very quickly determine the diameter of the hole and the wire as well as the character of the wire. Very often a screen with supposedly square openings shows holes that are of many different shapes.

Of the above methods suggested the approximate analysis of products from concentrating machines offers the largest field for the use of the microscope because here the instrument is a time saver for the experimenter as well as for the chemist. The products to be examined include sands and slimes from various types of machines such as tables, vanners, stamps, fine crushers and flotation machines.

Flotation offers a very big field, for in testing the amenability of certain ores to the process, we must determine the effect of numerous variables, including the effect of hundreds of oils. In testing, as well as in actual working machines, we get a froth which is the concentrate. This froth is very deceptive as to its mineral worth and without a microscope a visual analysis does not always suffice, so when a microscope is not available it is necessary for the chemist to make the proper determination. In testing an ore the chemist will have some 500 to 1000 determinations to make, 80 per cent of which could be eliminated by the use of a microscope. Not only could a large part of the chemical analysis be done away with but the experimenter in examining the froths could study more closely the work of the machine and the nature of the process.

The testing with a microscope is only the work of a few minutes and can be done on the wet ore if the results need not be accurate; or upon the dry ore if a more accurate check is desired. The manipulation is as outlined under method number three.

It is to be remembered that this work is only as accurate as the operator makes it, the degree of accuracy of course being limited and depending upon the experience of the operator.

The above suggestions as to the uses of the microscope in ore dressing are not by any means all new ones, but it is hoped that these may prove interesting as well as useful to those who are less familiar with the microscope.

CHAS. Y. CLAYTON.

## Copper in Converter Slags

*To the Editor of Chemical & Metallurgical Engineering*  
SIR—The editorial in the April 15 number of METALLURGICAL AND CHEMICAL ENGINEERING on "Copper in Converter Slags," is very interesting, and one that should bring out some discussion from metallurgists who have to solve the problem of cleaning converter slags.

I herewith give the results of some experiments made by me on the pouring of converter slags into blast furnace settlers which may be of interest.

|                                                        | Copper<br>Per Cent |
|--------------------------------------------------------|--------------------|
| Experiment No. 1.                                      |                    |
| Furnace and converter slag, proportions 1:1 assay 0.61 |                    |
| Furnace slag alone .....                               | 0.31               |
| Difference .....                                       | 0.30               |

|                                                         |      |
|---------------------------------------------------------|------|
| Experiment No. 2.                                       |      |
| Furnace and converter slag, proportions 2:1, assay 0.53 |      |
| Furnace slag alone .....                                | 0.41 |
| Difference .....                                        | 0.12 |

|                                                         |      |
|---------------------------------------------------------|------|
| Experiment No. 3.                                       |      |
| Furnace and converter slag, proportions 3:1, assay 0.54 |      |
| Furnace slag alone .....                                | 0.40 |
| Difference .....                                        | 0.14 |

|                                                         |      |
|---------------------------------------------------------|------|
| Experiment No. 4.                                       |      |
| Furnace and converter slag, proportions 4:1, assay 0.63 |      |
| Furnace slag alone .....                                | 0.47 |
| Difference .....                                        | 0.16 |

These experiments were checked several times, and showed that the converter slag was not cleaned below approximately 1 per cent copper by this method which together with the fact that the excess iron contained was valuable as a flux, finally resulted in all the converter slag being resmelted in the blast furnaces, the limestone being taken off the charge, and both costs per ton of charge and metallurgical losses materially reduced. At first the converter slag was spilled on the ground and picked up by hand labor, but this was afterwards changed to simply spilling it in thin layers on the ore in the pits as the beds were being built for smelting, the plant lending itself peculiarly to this method of handling the slag.

Most metallurgists will, I think, admit that converter slags cannot be cleaned without resmelting them, and in doing so, changing the chemical composition, but it will be interesting to get the experience of those who have had to treat them by other methods and especially of those who, on account of their plants are forced to spill the slag into reverberatory furnaces.

FOREST RUTHERFORD.

[We invite further discussion of this interesting subject.—EDITOR.]

## Condensation in Electric Zinc Smelting

*To the Editor of Chemical & Metallurgical Engineering*  
SIR—In your issue of May 15, 1918, page 540, in the article on Fulton's Electric Zinc Furnace, the following didactic statement is made: "Several designs of electric zinc furnaces can produce zinc vapor in large quantity, but none of them has been able to produce the proper yield in liquid metal." I have no knowledge of how inclusive the said "several designs" may be; but

as the evident intent is to convey the impression that the Fulton furnace, or its condenser, is the first to successfully accomplish the indicated result, I beg the privilege of informing you that this is not in accordance with the facts.

For some ten or more years past, I have been engaged as a principal in the design and development of electric furnaces for reducing zinc ores, complex and oxidized the principal work being carried on in Europe, or until suspended by the war. Hundreds of tons of high-grade zinc was produced, the condensation being approximately completely in the form of liquid metal. The reduction was according to the classical formula

More recently, or about two years ago, I designed and caused to be built and operated an electric furnace and condenser for refining impure spelter by re-distillation. The overall dimensions of this unit, in plan, were about 5 x 8 feet, height 4 feet, and it was run for months continuously with a regular output in refined zinc of 2,500 pounds in 24-hours, and in one case at the rate of 3,600 pounds. The condensation was complete to liquid metal.

Incidentally, the upkeep cost was *nil*. The electric energy required for this operation ran from about 0.5 to 0.6 kw.-hr. per pound of refined metal and in a regular "going" operation could probably be reduced to 0.4 kw.-hr., which is sufficiently near to the theoretical limit, as in "the books," to be dubbed good enough.

That the work was carried through with care, skill and intelligence, and with a docket record which is complete, goes without saying in that it was conducted by Mr. F. A. J. FitzGerald, E.E., at his laboratories, Niagara Falls, N. Y.

The project, as relates to zinc-smelting, has not as yet been exploited in this country, nor am I seeking by this means to advertise it; the limited details herein set forth are presented simply to accentuate the point that a little condensation of such a sweeping statement as you stand sponsor for would appear to be in order in the interest of accuracy and fairness.

JOHN THOMSON.

New York City

## Special Gold-Recovery Processes

To the Editor of Chemical & Metallurgical Engineering

SIR—In your issue of June 1 Mr. Kirby Thomas calls attention to the fact, reported by John Mawe a century ago, that Brazilian natives mixed the juice of certain bruised herbs with the water in which they finished the panning of gold from black sand, and also mentions the addition of the leaves of an oak-like tree to *tahones*, or primitive Chilean mills, used for grinding ore in Sinaloa, Mexico. This use of plant juice to facilitate the settling or concentration of "float" gold has been mentioned by several other writers.

Volume 20 of the Proceedings of the Institution of Mining and Metallurgy (1911) contains two papers on the Passagem and Ouro Preto mines in the province of Minas Geraes, Brazil. One of these, by R. H. Kendall, describes (pp. 28-60) the modern treatment of the bismuthic gold ore of Ouro Preto by stamp-milling and concentration on blankets followed by Frue vaners. The very rich blanket concentrate (largely free

gold) is re-washed over a small blanket, yielding a final concentrate carrying about 80 per cent gold. "The water used in this operation is a solution containing the juices of the leaves of the *jurupeba*, and is very effective in preventing float gold. . . . At the end of each day's operation the *jurupeba* solution is filtered off by suction and stored for next day."

In discussing this paper, H. L. Sulman, president of the Institution, called attention to the use of this herb—presumably containing saponin—which he interpreted as reducing the surface tension of water. Sulman, by the way, was an oil and soap chemist and an early experimenter in flotation, who had previously patented the use of soap solution for settling float gold and slime (Brit. pat. 24,939, of 1893 and 8,405 of 1894). The plant was stated to be *Solanum paniculatum*, of the nightshade or potato family, and also locally called *hera de sabão* (soap plant). Other plants, including a variety of passion-flower, were also said to be employed for the same purpose in the district referred to above.

The same thing had also been recorded by Alexander Calcleugh ("Travels in South America, 1819-1821"; published in London, 1825). A. G. Lock ("Gold", p. 227) says: "The overseer showed Calcleugh some plants whose juice is squeezed into the bowls containing gold, to carry down the lighter particles. There were several plants in common use for this purpose, but the one generally preferred, from its containing more juice, was called *itabamba*; it appeared to be a *Solanum*. The leaves had a bitter taste and gummy feel." This was at a place one league from Passagem.

In the Philippine Islands a pod-bearing vine (*Entada Purusaetha* or *Entada scandens*, called *gogo* or *balogo* by the natives) is used in panning gold with the batéa. This contains saponin and was the subject of an investigation and report by the Philippine Bureau of Science a few years ago. It was also mentioned by Lock ("Gold", p. 368).

Something similar has, I believe, been reported as used by the native gold-washers of Sarawak (Borneo) and Sumatra; I have also heard vaguely of an herb used by Mexicans in California and Lower California. The latter is probably one of several well known liliaceous plants called soap-root or *amolè*, the roots of which contain enough saponin or allied substance to lather freely with water.

Saponin as an anti-flotative agent has been discussed to some extent by Hoover, Rickard, and other writers on flotation. It evidently occurs in plants differing widely in character and distribution, which include the horse-chestnut and the numerous soap-roots, soap-barks, soap-berries, etc. Its application to float gold appears from the above to be confined to people of a relatively low stage of civilization. It would be interesting to ascertain whether such remote races as the Brazilians and Filipinos discovered it independently, or whether, as Mr. Thomas suggests by the heading of his letter, they both learned its use from the early Portuguese or Spaniards who employed them in mining. That it "works" is evident from its continued use in Brazil for a hundred years.

# Western Metallurgical and Chemical Field

## Price Fixing in Zinc, Copper and Aluminium

THE President has approved various agreements entered into between the price-fixing committee of the War Industries Board and interested producers and consumers. Prices on grade A zinc are continued at 12 cents per pound, f.o.b. East St. Louis until Sept. 1, 1918, while 14 cents per pound f.o.b. plant for plate zinc more than  $\frac{1}{8}$  inch thick and 15 cents per pound for sheet zinc subject to the usual trade discounts and extras in effect Feb. 13, 1918, will be the official price until the same date. The expectation of the miners and producers of prime western that a price of 11 cents would be fixed for second grade zinc was thus disappointed.

Following is the specification for spelter for navy requirements, as announced by the Government:

### SLAB ZINC

#### GENERAL SPECIFICATIONS

1. General specifications for inspection of material, issued by the navy department, in effect at date of opening of bids, shall form part of these specifications.

#### GRADES

2. There shall be three grades of spelter, grades A, B and C, respectively, conforming to the requirements stated below.

#### QUALITY

3. "Only virgin spelter, that is, spelter made from ore by a process of direct reduction and distillation, redistillation, electrolysis or a combination of the above shall be furnished in grades A and B. Metal produced by the refining of by-products such as brass mill wastes or other by-products resulting from the manufacture of non-ferrous alloys or similar materials, will not be accepted under Grades A and B."

#### CHEMICAL REQUIREMENTS

4. The chemical properties of the several grades of slab zinc shall be as follows:

#### GRADE A

|                                                           | Per Cent |
|-----------------------------------------------------------|----------|
| Zinc, minimum .....                                       | 99.85    |
| Cadmium, maximum .....                                    | .05      |
| Iron, maximum .....                                       | .03      |
| Lead, maximum .....                                       | .07      |
| Sum of cadmium, iron and lead, maximum .....              | .10      |
| Aluminium, maximum .....                                  | None     |
| Other elements—tin, arsenic, sulphur, antimony, etc. .... | None     |

#### GRADE B

|                                                           | Per Cent |
|-----------------------------------------------------------|----------|
| Zinc, minimum .....                                       | 99.35    |
| Cadmium, maximum .....                                    | .50      |
| Iron, maximum .....                                       | .03      |
| Lead, maximum .....                                       | .20      |
| Sum of the cadmium, iron and lead, maximum .....          | .50      |
| Aluminium maximum .....                                   | None     |
| Other elements—tin, arsenic, sulphur, antimony, etc. .... | Traces   |

#### GRADE C

|                                                           | Per Cent |
|-----------------------------------------------------------|----------|
| Zinc, minimum .....                                       | 98.00    |
| Cadmium, maximum .....                                    | .75      |
| Iron, maximum .....                                       | .08      |
| Lead, maximum .....                                       | 1.00     |
| Sum of cadmium, iron and lead, maximum .....              | 1.50     |
| Aluminium .....                                           | Traces   |
| Other elements—tin, arsenic, sulphur, antimony, etc. .... | Traces   |

The War Industries Board advanced the price of copper to 26c. on July 2. Where contracts for brass tubings, wire, etc., had been made at the 23 $\frac{1}{2}$ c. figure the old prices should prevail until August 15.

A new price for aluminium, effective from June 1 to Sept. 1, 1918, is 33 cents per pound, f.o.b. smelter, 93 to 99 per cent ingot, in lots of 50 tons or over. Differentials for quantity, grade, and alloys remain as before, while differentials for sheets, rods, and wire are increased approximately 12 $\frac{1}{2}$  per cent.

## Work of the Colorado Station of the Bureau of Mines

During the past year at the Bureau of Mines' Experiment Station at the State School of Mines, Golden, Colorado, under the direction of R. B. MOORE, the coöperative work in connection with the National Radium Institute has been completed, and over eight and one-half grams of radium element recovered. The larger part of this radium goes to the officials of the National Radium Institute, who will use it for cancer work. Part of the balance was retained as its share of the work and will be held at the Colorado station for scientific research; a part was presented to the Bureau of Standards, and the rest of it will be at the call of the Army or Navy hospitals. This coöperative work has given the Bureau an excellent opportunity to study the technical and scientific problems connected with the manufacture of radium from carnotite ore.

In addition to carnotite, another uranium mineral, pitchblende, is found in appreciable quantities on Quartz Hill, near Central City, Colo. Two of the mines were formerly owned by Mr. A. I. DuPont, and during his operations a considerable amount of ore was mined and this was ultimately turned over to the Bureau of Mines under a coöperative agreement for experimental purposes. The material was used for a thorough investigation of the best methods of concentration of the low-grade ores and the extraction of radium and uranium. The solubility of radium sulphate in water and in different concentrations of sulphuric acid has been determined, and the results published. This work has a distinct bearing on the precipitation of radium from solutions in plant operations.

The recovery of two other radioactive elements—ionium and actinium—from radium-bearing ores is also being investigated. If these elements could be produced commercially along with radium, they could be substituted for radium in luminous paint, and in other ways. A redetermination of the ratio of radium to uranium in primary uranium minerals will be started shortly. This will have a bearing on the whole question of radium recoveries in the treatment of radium ores, as well as a very definite scientific value.

Many manganese ores carrying silver cannot successfully be treated by cyanidation, the extraction of the silver being altogether too low. Under a coöperative agreement with the Dutch government, a thorough investigation of the treatment of certain of these ores by means of the Caron process is now being carried out. This process involves a preliminary reducing roast, by which the silver extraction can be raised and a satisfactory recovery obtained by cyanidation. It is probable that the scope of this investigation will take up the whole question of leaching manganese ores, and the re-precipitation of the manganese.

Under a coöperative arrangement with the Welsbach Company mesothorium is being investigated, and a

method for the recovery of this element as a by-product in their manufacture of thorium nitrate has been worked out. This mesothorium, which has in the past gone to waste, will ultimately be used for luminous paints for various objects, such as instrument dials, as well as for therapeutic purposes.

The Colorado Station has been particularly interested in molybdenum, and has not only worked on a soluble molybdenum ore from near Ouray, both as regards its composition and treatment, but also has been interested in the concentration and metallurgy of wulfenite and methods of separating molybdenite from copper-bearing minerals. The best conditions for the reduction of tungstic acid to metallic tungsten have been worked out, and results will shortly be published. Work has also recently been started on the metallurgy of certain vanadium minerals, such as vanadinite and cupro-desclowitzite.

### A Tariff or a Bounty on Antimony

The difficulty in imposing a rational tariff on antimony according to the rule—cost of foreign production plus tariff equals American cost—is glimpsed when one understands that the cost of Chinese antimony is unknown except perhaps to the Chinese (and they are not telling), while American mining and smelting are both in such an embryonic condition that even the potential operators do not know what it will cost them on a basis of quantity output. Certain it is that the price of Chinese antimony has fluctuated over such wide ranges in the past years that one suspects speculation by brokers or else market manipulation by those controlling the bulk of the supply. A successful corner in a metal so widespread and so easily won as is antimony, appears to be improbable; on the other hand, more than once in the past 25 years have western miners been enticed by high antimony prices to get small properties to the production stage, then only to find a prohibitively low price.

As is natural at any tariff hearing, many divergent views were expressed by those present at a recent conference with the Tariff Commission in San Francisco. All present (except the importer of Chinese metal) agreed that American antimony could be produced in sufficient quantity at 16 cents; on this basis the miner could receive \$85 a ton for a 50 per cent concentrate, leaving 7½ cents per pound to cover the cost of smelting and selling the metal. This latter item is said actually to cost 5½ to 6 cents at the Los Angeles works of the Western Metals Company. The miner was careful to emphasize, however, that a sufficient tariff wall should be erected against the importation of ore, else by treating cheap foreign ore the smelter would reap all the benefit and the miner none.

The United States' consumption of antimony is moderate. Pre-war requirements amounted to about 7000 tons of metal per year, of which 3000 tons were produced as a byproduct of the refining of antimonial-lead. It is largely used for hardening lead—in the manufacture of bullets, bearing metal and type metal. The present consumption has doubled the demand; it now probably amounts to about 1500 tons per month.

From the facts just indicated, i.e., ignorance of actual production costs, the moderate amount required of this very widespread metal, and its acknowledged impor-

tance in munitions, the tariff commission may with reason recommend that the War Industries Board solve the riddle by offering to purchase for a period of years the munition requirements of American made metal from American ores at a price covering cost plus a reasonable profit. During that time the operations of this industry, then passed from embryonic to the infant stage, can be studied and proper measures taken to insure its continuance.

### Company Reports

**Inspiration Consolidated Copper Company.**—Notwithstanding a strike lasting two months, and a considerably reduced scale of operations for the remainder of the year, Inspiration mined 3,914,742 tons of ores from which 80,566,982 pounds of refined copper was produced, which netted an average price of 26.366 cents. The cost of production, exclusive of depreciation and federal income tax, is tabulated as follows:

|                                                | Cost per lb. | Cost per Ton |
|------------------------------------------------|--------------|--------------|
| Mining.....                                    | 3.572c.      | \$0.7239     |
| Coarse crushing.....                           | 0.163        | .0329        |
| Ore hauling.....                               | 0.101        | .0206        |
| Concentrating and royalty.....                 | 2.951        | .5941        |
| Concentrates hauling.....                      | 0.007        | .0015        |
| Smelting, freight, refining and marketing..... | 3.665        | .6369        |
| Total.....                                     | 10.439c.     | \$2.0099     |

The grade of the ore was purposely dropped to 1.388 per cent copper, containing 0.279 per cent oxide copper, from which 20.39 pounds of copper was recovered. This recovery figures to a little over 75 per cent of all copper, but nearly 90 per cent on the sulphides contained. Important experimental work to increase this recovery was continued, indicating the desirability of retreating sand and slime separately, floating the sulphides from the former followed by a roasting and leaching operation similar to that practiced at Anaconda. The slime, containing a large proportion of the oxides, is to be leached with sulphuric acid. The success of the Ajo plant of the New Cornelia Copper Company treating ores very similar to the 20 million tons of oxides on Inspiration ground seems to settle the question of treatment of these reserves. During the year a new chemical laboratory was constructed at the concentrator, the filter plant was increased 50 per cent, a 200-ft. concrete tank for tailing settlement built, and two additional units added to the mill.

Additional data on the operation of the mill follow:

|                                                                             |      |          |
|-----------------------------------------------------------------------------|------|----------|
| Water Consumption for First Six Months of Year per Ton Ore Milled:          |      | Gal.     |
| Reclaimed in tanks at foot of mill.....                                     |      | 356      |
| Reclaimed in tailings ponds.....                                            |      | 475      |
| New water from Kiser pump station.....                                      |      | 277      |
|                                                                             |      | 1,108    |
| Power Used per Ton Ore Milled for First Six Months of Year:                 |      | Kw.-Hr.  |
| Coarse crushing.....                                                        |      | .43      |
| Fine grinding and concentrating.....                                        |      | 10.87    |
| Blowers for flotation air.....                                              |      | 2.42     |
| Filter and reclaiming water.....                                            |      | 2.01     |
| Lights.....                                                                 |      | .07      |
| Total.....                                                                  |      | 15.80    |
| Steel ball consumption in fine grinding, per ton ore milled (for year)..... |      | 1.82 lb. |
| Flotation Oils per Ton Ore Milled:                                          |      |          |
| Cost tar—lb.....                                                            | 1.21 |          |
| Sundry oils—lb.....                                                         | .11  | 1.32 lb. |

**Phelps Dodge Corporation.**—The concentrator at the Morenci branch treated 312,224 tons of ore containing 2.333 per cent copper, producing concentrates averaging 11.201 per cent copper, and a tailing averaging 0.648 per cent copper, a saving of 71 per cent, on a concentration ratio of 6.78. The metallurgical results here are unsatisfactory owing to inefficient labor, and

irregular and inadequate power, the mill having operated but 54 per cent of the time. An extension to the flotation department is under way, which is designed to increase the savings. Somewhat the same metallurgical conditions obtain at the mill of the Moctezuma Copper Co., where 750,897 tons of ore containing 3.179 per cent copper were treated producing a tailing of 0.747 per cent copper—a saving of 81 per cent. These operations were uninterrupted throughout the year, however, and the net production of 38,186,451 pounds of copper exceeded the previous maximum by over two million pounds of copper. Experimental work is to be continued on the slime, together with other tests to reduce loss in sand-tailing by fine grinding. At the Bunker Hill mines, Tombstone, Arizona, experimental work for the treatment of low-grade gold-silver-lead ores by flotation was unsuccessful owing to high operating costs and poor extraction. Half the mill capacity was used in making manganese dioxide concentrates, which operation produced a silver-bearing tailing suitable for flux. Eleven tons of wulfenite concentrates carrying 2106 pounds of molybdenum were also shipped. Labor troubles in the Bisbee district did not affect the production of the Copper Queen smelter at Douglass, owing to the stocks on hand and the increased shipments from Burro Mountain, Moctezuma, and the United Verde Extension, so that the total output shown below was the largest in its history by a margin of almost 20 million pounds.

|                          | Dry Tons<br>Charged | Ounces<br>Gold | Ounces<br>Silver | Pounds<br>Copper |
|--------------------------|---------------------|----------------|------------------|------------------|
| Copper Queen branch..... | 794,904             | 19,171         | 559,156          | 87,831,317       |
| Burro Mt. branch.....    | 45,868              | 293            | 36,799           | 13,342,508       |
| Moctezuma Copper Co..... | 167,381             | 1,910          | 508,387          | 38,499,781       |
| All other.....           | 268,064             | 10,937         | 946,921          | 31,907,525       |
| Total, 1917.....         | 1,276,817           | 32,331         | 2,042,263        | 191,581,131      |

Offerings of custom ores were more than could be accepted. Minor changes in the various departments are expected to increase substantially the capacity during 1917. The record production of copper was effected with but one fatal accident in the smelting departments.

**Judge Mining and Smelting Co.**—The mill at Park City, Utah, treated 63,387 tons of ore in 501 shifts, producing 11,861 tons of lead concentrates and 5526 tons of zinc concentrates. The electrolytic zinc plant has been continuously and successfully operated since the start, early in the year. The production has been small, however, owing to the impossibility of obtaining desired reagents for the purification of the solutions. This difficulty has been largely eliminated by changes in methods employed, and with a good price fixed for Grade A zinc, production should proceed at the designed capacity.

**Goldfield Consolidated Mines Co.**—The activity of this company is summarized as follows: 250,550 tons of ore was treated, containing \$2,039,103 in metal value, and yielding \$1,762,970; and 81,885 tons of tailings containing \$103,843, of which \$62,326 was recovered. Two-thirds of this production was cyanided, and the balance treated by the flotation process. The latter, operating on low-grade copper ores, has been in continuous service since opening in March. The concentrates are now shipped to custom smelters, since three months' experience with a local concentrate-treatment plant proved unsatisfactory, and tests indicated that they cannot profit-

ably be cyanided without a chloridizing roast. The company has opened a store for the purpose of reducing the cost of living, with pronounced success and unqualified approval from the employees. All business is conducted on a cash basis, and a preferential discount of 10 per cent given to employees. The cost of operation including the discount is 19 per cent. of the total sales, and the department sustained a loss of \$4000 in ten months' operation. The appended tabulation shows very graphically the trend of the company's operations, and about the middle of the year it became apparent that the ore exposed would not yield a profit. Later development work is distinctly encouraging, however. Nevertheless a statement of recoverable assets and the scrap value of the equipment after operations have ceased includes the following items:

|                             |             |
|-----------------------------|-------------|
| Scrap value of plant.....   | \$250,000   |
| Mill clean-up.....          | 100,000     |
| Profit from subsidiary..... | 300,000     |
| Profit from mine.....       | 200,000     |
| Profit from tailings.....   | 500,000     |
| Supplies and stores.....    | 330,000     |
| Cash and investments.....   | 551,000     |
| Total.....                  | \$2,431,000 |

which could be realized during a period of about six years. The following comparative data are interesting:

|                                   | Average<br>Recovery | Average<br>Cost | Net     |
|-----------------------------------|---------------------|-----------------|---------|
| Year ending Oct. 31, 1909.....    | \$34.72             | \$8.88          | \$25.84 |
| Year ending Oct. 31, 1910.....    | 38.50               | 10.97           | 27.53   |
| Year ending Oct. 31, 1911.....    | 30.74               | 7.97            | 22.77   |
| 14 mos. ending Dec. 31, 1912..... | 18.40               | 6.65            | 11.75   |
| Year ending Dec. 31, 1913.....    | 14.14               | 6.32            | 7.82    |
| Year ending Dec. 31, 1914.....    | 11.61               | 6.19            | 5.42    |
| Year ending Dec. 31, 1915.....    | 9.01                | 5.02            | 3.99    |
| Year ending Dec. 31, 1916.....    | 6.53                | 5.18            | 1.34    |
| Year ending Dec. 31, 1917.....    | 7.64                | 6.01            | .68     |

**The Consolidated Mining and Smelting Company of Canada, Ltd.**—Reminders of the recent acute state of the Canadian lead market are contained in the report of this company, operating the Trail smelter, showing a large bank overdraft (\$2,081,806.24) which the president of the company, MR. W. D. MATTHEWS, states is due to the unusual accumulation of ores in anticipation of the needs of the Imperial Munitions Board. Overbalancing this is metalliferous material valued at \$2,615,664.17, subdivided as follows: Pig lead on hand and in transit to refineries, \$29,242.95; ores on hand, \$1,502,698.20; refinery metals on hand, \$1,014,819.10, and ore in transit to smelter, \$68,903.92. The last year has been one of extraordinarily diversified activities at the smelter, the construction ending Sept. 30, 1917, totalling \$1,442,883.12. The electrolytic zinc plant was completed, and a daily production of over 60 tons of pure zinc reached, while a 400-ton concentrator was erected to treat the Sullivan ores. In the lead plant the new bedding system was completed, and a record production of 22,133 tons metal attained with the best metallurgical results in recent years. The sulphuric acid plant was doubled in capacity, and now produces thirty tons of chamber acid per day. After supplying the entire needs of the refineries and the zinc plant, there is a surplus for commercial sale. The hydro-fluosilic acid plant produced 196 tons of 100 per cent acid, providing the entire requirements of the lead refinery. Two new retorts are now under construction, to double the capacity of this plant. Taking these departments into consideration, the Trail plant is producing on a commercial scale bluestone, sulphuric acid, hydro-fluosilic acid, gold, silver, copper, lead and zinc.

## The President's Readjustment and Reconstruction Commission—III

BY WINGROVE BATHON

Washington Correspondent, McGraw-Hill Co., Inc.

**F**OLLOWING the presentation in McGraw-Hill Engineering Publications of a concrete plan for a proposed Readjustment and Reconstruction Commission to be appointed *now* by the President of the United States, to deal *now* with problems which will be presented to American Industry after the war, it has become known in Washington administrative circles, in an unofficial manner, that a plan for a readjustment and reconstruction agency is under consideration.

### COUNCIL OF NATIONAL DEFENSE STUDYING PROBLEM

It is permitted to say here publicly for the first time that the Council of National Defense has been studying the subject of readjustment and reconstruction for a lengthy period, with a view to co-ordinating various Government activities in Washington which have had readjustment and reconstruction for their object. When President Wilson recently set up the War Industries Board, under the chairmanship of Mr. Bernard M. Baruch, as a separate agency, divorcing it from the Council of National Defense, the latter organization was left with but little work to do, and with but few prominent men remaining in its personnel. There is reason for the belief that the Council of National Defense has resolved to undertake the work of readjustment and reconstruction, if permitted to do so by President Wilson, and there is also reason for the belief that the President will assent, under the urging of Secretary Baker of the War Department, chairman of the Council, acting in behalf of himself and the other five members of President Wilson's cabinet who compose the Council of National Defense.

In Washington official circles there is an impression that this would be a logical step, inasmuch as a number of cabinet officials have begun making public details of readjustment and reconstruction ideals upon which their own departments and bureaus have been separately at work, following the advocacy of such a readjustment and reconstruction agency in McGraw-Hill Engineering Publications. There is ground also in Washington not only for the impression but for the strong belief that if the Council of National Defense is authorized by the President to begin work on readjustment and reconstruction problems, W. S. Gifford, Director of the Council, will not only set to work at once to co-ordinate all the work being separately done in the various departments but will undoubtedly call into consultation and activity at Washington men in private industry of the type suggested in the first article in this series which was put forth as a method of crystallizing opinion in favor of a readjustment and reconstruction agency and obtaining action to create one. In other words, it is in expectation in Washington that, if the President assents, the Council of National Defense will be newly created by the appointment of a large number of committees of important men of the type suggested in the first article in this series, taken from the ranks of private endeavor, to solve now the after-the-war industrial problems of this country, as England is now doing.

Before this is published, the question of what char-

acter of readjustment and reconstruction agency shall be established may have been settled. It is possible that when the announcement of the Government's intentions in this respect is made, it will have been found after due consideration that it might be more wise to commit the work of readjustment and reconstruction to an agency other than the Council of National Defense; but the subject is now being discussed on all sides in Washington, and letters and telegrams from all over the country are being received in Washington urging the creation of such an agency at once.

From Philip H. Gadsden, chairman of the National Committee on Public Utility Conditions, comes a letter strongly indorsing the idea of action. The National Committee on Public Utility Conditions, which includes E. K. Hall, H. H. Crowell and A. S. Hills, executive secretary, represents in Washington the National Electric Light Association, the American Electric Railway Association, the American Gas Institute, and the National Commercial Gas Association. Mr. Gadsden says:

"It is coming, I think, to be more and more generally realized that the problems which the industrial world will have to face after the war in the readjustment of our economic life will be more serious than even the problems which we are now called upon to meet. Your suggestion, therefore, that the President at this time appoint a Commission on Readjustment and Reconstruction, in my judgment, is a very timely one.

"The great lesson which this war has impressed upon every one is the efficiency resulting from great concentration of capital and labor. The benefits derived by the nation for war purposes in the mobilization of practically all the industries of the country will not be lost sight of when peace comes. To deal properly with such a radical change in our economic policy will call for all the wisdom at our command. Nothing could aid so much in the proper solution of such a problem as a thorough and comprehensive study of it in advance, such as you suggest."

From the Permutit Company, engaged in water rectification and general sanitation, New York, comes this letter, signed by Samuel Robert, President of the Company:

"As we see it, there can hardly be room for doubt as to both the usefulness, and, indeed, the necessity, for the work of the nature referred to, and that this work should be done as quickly and as thoroughly as possible.

"We can think of no better way to prepare the ground work essential to the proper accomplishment of this vital project (vital to the future benefit of the industries of this great country) than by having a commission appointed as quickly as possible for the express purpose of investigating the necessary steps needed to prepare for its accomplishment, and then to put into effect as thoroughly as possible the means needed for its fulfillment. We are in hearty accord with this movement."

### DEMANDS OF RECONSTRUCTION PERIOD NOT APPRECIATED

From Charles F. Lang, President of the Lakewood Engineering Company, Cleveland, Ohio, comes this letter:

"While our company is working night and day on war service for the Government, and is constantly endeavoring to expand its usefulness in this direction, all our planning is being done with a view to world-trade conditions after the war, for we feel that we but dimly realize the demands which world-trade will make upon American manufacturers in the reconstruction-period immediately following the war.

"And we also recognize the period of tremendous readjustment which must take place in our own country. National conditions and national ideals are entering a violent revolution rather than a slow evolution, and I sincerely trust that the very constructive program suggested by you will receive serious consideration and prompt action on the part of the Government; for the

problems involved are not merely national, but world problems; and individual thinking by individual business men is hopeless—the nation must think and plan *as a Nation.*"

From the great merchandising house of William Filene Sons Company, Boston, Mass., comes this letter, signed by Edward A. Filene, its President, who is Chairman of the War Shipping Committee of the Chamber of Commerce of the United States:

"I am in entire agreement with your suggestion that such preparation should be under way. Unless there is created a Governmental Agency for this undertaking, an agency thoroughly representative of all classes and interests, these problems will be taken up separately by the various classes and interests."

#### UNITY OF PURPOSE VITAL TO WELFARE OF COUNTRY

"If the bulk of the reconstruction planning is left to separate classes and interests, we shall come to the end of the war with a series of reconstruction programs. Business will have a program; labor will have a program; agricultural interests will have a program; banking interests will have a program; socialists and holders of relating theories will have a program. And, at the very moment when unity of purpose and promptness of action will be vital to the welfare of the country, we shall be obliged to pay the price of costly delay incident to the harmonizing of these several programs of reconstruction.

"It is clearly the wise policy to create a government commission so thoroughly representative of all classes and interests that it will command the support of all classes and interests. If such a commission collates its facts, formulates its conclusions, and submits them in advance to the most exhaustive criticism from all possible angles, we shall be able to get most of the work of compromise out of the way by the end of the war and arrive at the time of action with a unity of purpose and policy otherwise impossible.

"I realize the question of tactics and timeliness involved in any proposal today not related to the immediate job of prosecuting the war; and yet, the war will end some day, and whether that time be one year or twenty years from now, the time will be none too long for the analysis of the complicated problems that underlie the return of our social, industrial, and political life from a war basis."

#### Fourth National Exposition of Chemical Industries

THE Fourth National Exposition of Chemical Industries will be held in the Grand Central Palace, New York, during the week of Sept. 23 this year. The advisory committee is composed of Charles H. Herty, chairman; Raymond F. Bacon, L. H. Baekeland, Elwood Hendrick, Henry B. Faber, Bernard C. Heese, A. D. Little, Wm. H. Nichols, R. P. Perry, H. C. Parmelee, G. W. Thompson, F. J. Tone, T. B. Wagner and M. C. Whitaker. Dr. Bacon of this committee is now head of the Chemical Warfare Section of the National Army and a member of General Pershing's staff.

The coming exposition will be the largest chemical exposition ever held and it will be necessary to use four floors of the Grand Central Palace. Regarding the exposition as a war-time necessity, each exhibitor is planning an exhibit that will be of the greatest benefit to the country through the men who visit it, all of whom are bent upon a serious purpose—that of producing war materials in large quantities, and constantly increasing this production till the war has been won by the United States and its Allies.

The amount of floor space already engaged is greater than last year; the exhibits will be much more attractive and a movement is under way to show all exhibits of machinery in operation under actual working conditions

as they would be found in the field. The products of chemical manufacturing as they enter into the world's commerce will be shown as examples of what the chemist has produced in America since the world war began.

The South is again sending exhibits from some sections, and Canada, too, is taking the opportunity of presenting the materials it has available for development by the chemist and financier. Technical and business men over the country give heed to these exhibits since they will show how they can meet the war-time need. A section for the glass and ceramic industry has been added with which the American Ceramic Society is co-operating.

The program for the exposition is in active preparation and will be a series of symposia on the "Development of Chemical Industries in the United States, notably since July, 1914." This will embrace the period since the beginning of the European war, which by removing the source of supply for some of our domestic industries has inspired the development of our own chemical industry. The program of motion pictures carries forward the idea of the symposia.

#### War Industries Board Plans Conservation of Tin

THE plan upon which the War Industries Board is working for the conservation of tin is based on the conviction that no government official, department or bureau can be in position to apply restrictions to industries as wisely as the men who have spent their lives in the industries affected and are thoroughly acquainted with the technical details and the business consequences involved.

The Board calls meetings of representatives of each important trade using tin, states the necessity for economy, asks for patriotic coöperation and seeks advice as to how to get the results desired. Each industry is asked to organize, to consider the problem and submit specific recommendations. These recommendations are digested and sent to everyone in each trade concerned. Conferences are held with those who may not agree with the recommendations so as to get as complete unanimity as possible. A set of recommendations or regulations is then drawn up for each industry and these are enforced by the authority of the War Industries Board.

The various uses of tin by different trades are classified in an ascending scale of importance.

*First:* Wasteful uses due to carelessness, ignorance or indifference. Wastes due to faulty practice which might be cut off not only without injury to anybody but rather to the definite pecuniary advantage of manufacturers.

*Second:* Uses non-essential in character, such as the coating of articles with tin for ornamental purposes solely. Uses which could be cut off without injury to any individual or firm, provided all acted alike.

*Third:* The employment of tin for purposes which in themselves are useful and desirable, so that their elimination would involve a certain amount of sacrifice on the part of manufacturers or consumers; but which are in no way connected with the vital needs of the country in relation to the war.

*Fourth:* Uses directly for war purposes either by the

Government itself as a manufacturer of war materials or by manufacturers who are making war materials for the Government.

Uses under "first" and "second" can and should be cut off at once. Under "third" curtailment is not in itself desirable. It will result in a certain disorganization of industry and reduction in economic efficiency and ought to be avoided if possible. But the sacrifice will probably have to be made. Lastly, come the direct war requirements, which must be met in full or military efficiency will suffer.

The following results have already been accomplished:

### 1. SOLDER AND BEARING-METALS

*Standardizing.* There are scores of compositions used in bearings-metals and solder. The Bureau of Standards has completed an investigation of bearing metals and has suggested elimination of all but four grades. This recommendation was adopted by the meeting and it is stated that a saving of about 25 per cent in amount of tin will be effected. The Bureau of Standards is making similar investigations concerning solder. The can companies have reduced the percentage of tin in their solder to forty, thus saving from 8 per cent to 10 per cent without injury to the industry.

### 2. BRASS AND BRONZE INGOTS AND CASTINGS

Most of this business is directly or indirectly for Government account. Considerable reduction could be made in tin content without reduction of efficiency. Large savings have already been made by automobile and other machine manufacturers by substituting for all metal bearings, case bearings with thin lining shell ( $\frac{1}{16}$  in. to  $\frac{1}{8}$  in.) of high-grade babbitt. Straits tin is often specified on the assumption that it is the purest tin. Banca is even purer than Straits or Australian, and electrolytic tin is as pure.

Manufacturers of tinfoil and collapsible tin tubes have effected large savings by reducing the tin content, and by substitution of other materials for containers. A plan was suggested and is now being perfected for the recovery of a large part of the tin used in foil and tubes. Through a campaign of advertising, through notices on the packages, and other methods, consumers of articles packed in foil or tubes will be induced to save these articles and turn them in at the nearest Red Cross center as donations. Smelters and other users of tin will then purchase at market rates the lots thus collected by the Red Cross. It is estimated that this will recover some 3000 to 5000 tons of tin per annum, and bring the Red Cross an added income of from \$4,000,000 to \$5,000,000.

### 3. TIN PLATE

Plans for the conservation of tin plate have long been in the hands of the Committee on the Conservation of Tin Plate. In coöperation with the trades concerned large economies have already been effected. The manufacture of plate for many less-essential uses, such as roofing, for store boards, for fire doors, etc., has been eliminated by agreement. Tobacco manufacturers have just reached an agreement by which black plate will be substituted for tin plate for most tobacco cans, effecting a saving of probably 750,000 base boxes of tin plate per annum. In addition, the

quantity of plate required for export has been greatly curtailed by the regulations for the War Trade Board restricting export to plate which is to be used for specific war purposes.

## Post-War Problems of the Electrochemical Industry

The American Electrochemical Society will hold its Fall meeting at Princeton, N. J., Sept. 29 to Oct. 1, and is planning to devote one session to a consideration of the reconstruction and post-war problems of the industry. The status of all our industries after the war is a most important question and deserves careful study at this time. This is especially true of many electrochemical industries which the demands of the war have stimulated to a point of expansion far beyond the requirements of peace.

Many of these industries such as the chlorine and alkali industry, the ferro-alloy industry, the manufacture of electric steel and the carbide industry have undergone an enormous expansion. We shall have the problem of the disposition of Government-owned plants. We must develop new uses in the arts of peace for the products of our war plants. Most all of these questions of reconstruction and readjustments are pressing in view of the world-wide competition which will follow a declaration of peace. Other subjects are the future of air nitrates, the electric power situation and research after the war in its varied university, Governmental and industrial phases.

A topic of far-reaching importance is the future relations of technical men to the affairs of Government. Can the very important work of some of our technical boards be continued after the war and made to function with the administrative and legislative branches of the Government?

## How Great Britain is Handling Post-War Questions

The British Ministry of Reconstruction has just published a complete list of the various commissions and committees that have been set up, both within that ministry and within other ministries and departments of the British Government, to deal with questions which will arise at the close of the war. These commissions and committees, which have been appointed at different times since the war began, now number 87 and fall into 15 groups of which the following will be of interest to the metallurgical and chemical industries:

To create a committee representative of the chemical trades for the development of its own resources and the securing of co-operation of all engaged therein.

To consider the international competition to be expected in the metallurgical industries, and devise proper safeguards required to maintain their position.

To investigate various processes for nitrogen fixation, survey the raw materials required, investigate the production of cheap power, to carry out preliminary experimental work, and to advise as to proper conservation of nitrogenous compounds.

To consider carbonization of industrial and domestic fuel.

To institute research on the preparation and utilization of fuels.

To advise on research in metallurgy and glass making.

To investigate the preparation, properties and applications of abrasive and polishing powders.

To prepare a reference list of the composition, densities, and optical characteristics of vitreous compounds and cements for same.

To control researches in tin and tungsten.

To survey the lubrication field, institute research on problems involved, and to collect and review the chemistry of lubricants and oils.

To collect and review existing information on copper and zinc manufacture as a basis for future research, and to institute research into methods of making sound castings and brass tubing.

To formulate methods of improving permanently the relations between workmen and employers.

To advise as to the opportunities of post-war employment of women.

## Federal Supervision of Niagara Falls Power

AS announced in this journal, Dec. 1, 1917, the War Department took over the supervision of the supply of electrical power at Niagara Falls in November, under the immediate direction of Robert J. Bulkley and Brig. Gen. Charles Keller. The first result of the supervision was to requisition for the United States all power generated or imported by the Hydraulic Power Company and the Niagara Falls Power Company, both of Niagara Falls, New York, and distribute it to war industries. The War Department now announces that as a result of this supervision accurate knowledge has been obtained of the use of power generated in this country in the Niagara Falls district and that imported from Canada. This information shows that practically all the power available is used to aid the prosecution of the war, direct war industries securing an average of 85.29 per cent of the total power of the two requisitioned companies and an average of 54.29 per cent of the total power of the cooperating companies. Under war conditions the power supply falls short of the demand by about 200,000 horsepower, which amount is not based on new industries but is determined as the amount of power which could be absorbed by the industries now operating, were such a supply available.

Some of this shortage will be relieved by the proposed enlargements of the steam plants of the Buffalo General Electric Co., and the Niagara, Lockport & Ontario Co. Additions to these two plants will aggregate 62,000 horsepower. By means of a further development by the American hydro-power companies at Niagara Falls their existing supply of power, amounting to about 250,000 horsepower, will be increased by about 160,000 horsepower. Many prominent men believe that the total available water power should be put to use.

The increased allotments of power to the essential electrochemical industries in the Niagara district and to the plants devoted to the production of such essentials as ferrosilicon, electrodes, phosphorus, chlorine and abrasives have conclusively demonstrated the beneficial results of regulating and controlling the distribution of power.

## Governmental Control of Sulphur-Bearing Materials

THE War Industries Board has decided to take control of the production and allocation of sulphur, pyrites and coal brasses and has authorized Mr. William G. Woolfolk, commodity chief in charge of pyrites and sulphur, to act for the Board in controlling the production and distribution of sulphur materials.

It has been apparent for some time that the increasing consumption of sulphur-bearing materials would soon necessitate action looking toward the conservation of existing supplies and development of new sources. With this end in view the War Industries Board on May 29 requested the Chemical Alliance, Inc., to submit a plan covering the allocation of sulphur-bearing materials. The directors of the Alliance met on June 7 and decided to submit a plan. At the same time they invited the producers and consumers of sulphur-bearing materials to meet with them and approve or disapprove the plan. On June 11 the directors of the Chemical Alliance recommended the appointment of a committee to consist of three directors of the Alliance and a representative of the War Industries Board which should have charge of sulphur distribution. It appears that after receiving this report the War Industries Board decided to assume control for the Government. Mr. Woolfolk acting for the Board will avail himself of the assistance of the committee which the Alliance constituted at its meeting on June 7, which will probably comprise Messrs. A. D. Ledoux, W. D. Huntington and C. G. Wilson. Under the by-laws of the Alliance the president and vice-president act as *ex-officio* members of all committees. The committee will be known as the Committee on Production, Distribution, Control of Sulphur Materials.

## Classification of Productive Occupations by War Department

In the regulations announced by Provost Marshal General Crowder affecting all men of draft age it will be of interest to chemists and metallurgists to note the following occupations which are indicated as productive:

|                             |                     |
|-----------------------------|---------------------|
| Chemical engineer.          | Digger (mucker),    |
| Chemist or chemical worker: | Drill runner,       |
| Acids and dyes,             | Laborer,            |
| Analytical,                 | Mine foreman,       |
| Explosives,                 | Miner,              |
| Fireworks,                  | Powderman,          |
| General,                    | Quarry foreman,     |
| Inorganic,                  | Quarryman,          |
| Metallurgical,              | Timberman,          |
| Organic,                    | Topman,             |
| Poisonous gases.            | Track layer.        |
| Foundryman:                 | Mining engineer.    |
| Core maker,                 | Rubber worker:      |
| Cupola tender (melter),     | Bootmaker,          |
| Furnace and ladleman,       | General,            |
| Molder.                     | Tire repairer,      |
| Gas maker:                  | Vulcanizer.         |
| Acetylene,                  | Sheet-metal worker: |
| Hydrogen, oxygen,           | Coppersmith,        |
| Illuminating gas,           | Lead burner,        |
| Poisonous gas,              | Solderer,           |
| Metal finisher:             | Tinsmith,           |
| Brass,                      | Any other.          |
| Nickelplater,               | Welder (cutter):    |
| Niterbluer,                 | Aluminum welder,    |
| Polisher.                   | Autogenous or oxy-  |
| Millwright.                 | acetylene,          |
| Miner or quarryman:         | Electric,           |
| Blastor,                    | Flue welder,        |
| Crusher operator,           | Thermit welder,     |
| Demolition man,             | Any other.          |

## Price-Bidding in War Times

A Discussion of the Economic Principles Involved in Public Control of Industry Versus Unrestricted Competition—Effects of Price-Bidding on Labor and Production—Experience of Great Britain

By ROSWELL C. MCCREA

THE following quotations represent fairly well the prevailing economic philosophy of business men:

"The business of life is better performed when those who have an immediate interest in it are left to take their own course, uncontrolled either by the mandate of the law or by the meddling of any public functionary. The persons or some of the persons, who do the work, are likely to be better judges than the government of the means of attaining the particular end at which they aim . . . the individual agents have so much stronger and more direct an interest in the result, that the means are far more likely to be improved and perfected if left to their uncontrolled choice."

"*Laissez faire*, in short, should be the general practice; every departure from it, unless required by some great good, is a certain evil." (John Stuart Mill: *Political Economy*.)

"A market price . . . is a price fixed by the self-interest of buyers and sellers, each acting independently—that is, with *free competition* on both sides. The price thus fixed is generally an advantageous one for society. . . . If buyers are allowed to compete and force prices up at the very beginning of a scarcity, the advancing price at once operates as a warning to use the article economically. This of itself causes the article to hold out longer. It will also generally happen that the advancing prices lead the producers to send more goods to the market where higher prices prevail; and that long before the advent of actual famine new sources of supply are developed, by which the severest scarcity is avoided. If this result can be secured by a moderate advance in price, it is worth many times what it costs. For it must be remembered that high prices are not so much an evil in themselves, as an indication of an evil. If they exist in an open market, it shows that certain needs of the community are adequately supplied. It often happens that the higher prices serve as a natural cure for the underlying evil, and that the effort to force those prices down by custom or law prevents the evil from curing itself. If custom or law prevents buyers from paying a competitive price, it soon means that some buyers must go without things they very much want." (A. T. Hadley: *Economics*.)

This philosophy has recently come vigorously to the fore as a conclusive rejoinder to those who would safeguard public interests by regulating consumption, restricting competition and fixing price standards. Its basal assumption is that falling prices lead to reduced production. It has grown out of the observation of the proximate effects of price changes in a limited market, and takes little account of the causes and effects of changes in industrial technique or the underlying causes of productive efficiency. It posits a freely competitive organization, operating with mobile capital and labor units of constant efficiency, in which the profit incentive of rising prices stimulates the energies of producers already in the field and speedily draws into the competitive arena a host of new profit-seeking adventurers. The effect of this wholesome tendency is depicted as making for price-levels in which marginal costs are determinative and basal.

### OBJECTIONS TO PRESENT ACCEPTANCE OF DOCTRINE

A fundamental objection to the acceptance of this point of view for present purposes is that freely competitive conditions do not exist and that production

units are neither freely mobile nor constant in efficiency. The psychology of those whose capital or whose energies are thrown into production is a variable quantity, the functioning of which varies in degree with industrial and social conditions. Price changes are merely one set of these conditions and their influence may easily be overestimated.

A dominant characteristic of modern industry is its large degree of use of capital goods in highly specialized, fixed forms. The old economist reasoned in terms of the corner grocery store with its easily fluctuating stocks of goods, which could be built up or depleted in a week. The typical modern establishment is the railroad or mine or factory. Its organization cannot be built up in a day. This requires months, often years, of planning and of preliminary production. Once established, its destiny is largely fixed. Its range of alternative uses is narrow. This condition has a marked influence on the flow of capital into new channels of utilization. The man of small capital or of undemonstrated capacity is ruled out by the size of the stake he must lay to get into the game, and the man of tried capacity and large command over resources will transform the wealth he may control into fixed forms only on the assurance of a reasonable profit margin and of a market of measurable permanency. A steady flow of profits is the lure, and certainty in price may be more of a stimulus to extensions and improvements than fortuitously rising prices.

### FAVORED PRODUCERS PROFIT BY PRICE-BIDDING

As a fact, profits are quite as likely to result from lowered production costs, due to rising productive efficiency, as from rising price-levels. The latter may draw the productive margin to a lower level; but this may well be at the expense of possible output, if there is no accompanying improvement in methods of exploitation. The more advantageously situated production units will reap larger profits through an altered distributive alignment; but no appreciable augmenting of production is likely to result. Favored producers would be quite inclined by prevailing methods to make hay while the sun shines, while those on the margin who hesitate to make new fixed capital outlays would continue to hesitate. *Laissez faire* means hesitancy, and price-bidding means the swelling of the purses of more advantageously situated producers, without any corresponding increase of gross product. An established price, affording certainty for a reasonable period, would be much more likely to swell production. It would encourage the hesitant and by establishing a price norm would afford an incentive-laden standard by which to measure the effects of improvements in productive processes.

I have urged these considerations in hypothetical form. There are many historical, as well as contem-

poraneous illustrations of their truth. Permanent and substantial increases in the production of goods have come not from competitive price-bidding, but in consequence of the application of the fruits of experimental knowledge. Antecedent to every increase of production, changes in productive processes have occurred, and to these the augmented product should be credited. Increased production leads to falling prices. The former stands to the latter in the relation of cause and effect; rising prices and perennially growing production are not thus related. A seemingly paradoxical corollary of this thesis is that large fortunes have sprung from new products or new methods that have led to lowered prices rather than from increased prices accompanying stabilized production methods. The latter situation, where irremediable or unimprovable, has usually led to substitutions. We make a mistake in emphasizing fixed rather than variable conditions in economic reasoning. A current illustration is the food situation in Central Europe. Under the pressure of war, Germany did not trust to rising price-levels to assure her an

cheapness and plenty to the consumer. We can double the present agricultural output but only by methods which reduce its price."

#### HIGH PRICES VERSUS IMPROVED METHODS OF ORE TREATMENT

The same conclusion holds in the exploitation of underground resources. The uninitiated are apt to think of ore beds as of even composition, varying in thickness and in degree of advantage of location. Gradations of price are pictured, corresponding to the varying costs of exploitation of different beds. It is, of course, obvious that for the most part minerals are of uneven composition. At a given time the major portion of existing deposits may well be of too low grade to be worked at a profit. Rising prices make good mines more profitable, but do little to make the production of low-grade ores either abundant or profitable.

Low-grade ores come into use through new methods of extraction. The prodigious expansion of the steel industry has come, not because of increased prices of

TABLE I.

| Commodity                           | Amount Produced 1911 | Total Value   | Amount Produced 1914 | Total Value   | Amount Produced 1916 | Total Value     | Amount Produced 1917 | Total Value     |
|-------------------------------------|----------------------|---------------|----------------------|---------------|----------------------|-----------------|----------------------|-----------------|
| Wheat (bu.)                         | 621,358,000          | \$543,063,000 | 891,017,000          | \$878,680,000 | 636,318,000          | \$1,019,968,000 | 650,828,000          | \$1,307,418,000 |
| Corn (bu.)                          | 2,531,488,000        | 1,565,268,000 | 2,672,804,000        | 1,722,070,000 | 2,566,927,000        | 2,280,729,000   | 3,159,494,000        | 4,053,672,000   |
| Oats (bu.)                          | 922,298,000          | 414,663,000   | 1,141,060,000        | 499,431,000   | 1,251,837,000        | 555,928,000     | 1,587,286,000        | 1,061,427,000   |
| Rye (bu.)                           | 33,119,000           | 27,557,000    | 42,779,000           | 37,018,000    | 48,862,000           | 59,676,000      | 60,145,000           | 100,025,000     |
| Barley (bu.)                        | 160,240,000          | 139,182,000   | 194,955,000          | 105,905,000   | 182,309,000          | 160,646,000     | 208,975,000          | 237,559,000     |
| Potatoes, white (bu.)               | 292,737,000          | 233,778,000   | 409,221,000          | 199,460,000   | 286,953,000          | 419,333,000     | 442,536,000          | 545,865,000     |
| Rice (bu.)                          | 22,934,000           | 18,274,000    | 23,649,000           | 21,849,000    | 41,325,000           | 36,673,000      | 36,278,000           | 68,717,000      |
| Sugar (short tons)                  | 960,374              | 102,664,000   | 968,674              | 91,500,940    | 1,133,626            | 156,009,600     | 1,094,240            | 167,703,220     |

adequate supply of grain. She turned to a cheaper substitute. But for the potato Germany would before this have been starved into submission. Many of the productive potato lands were barren soil a century ago. Scientific experimentation adapted the potato to these waste regions, supplemented by soil analysis which afforded knowledge of added elements requisite for potato cultivation. Beyond the limits of any possible increase of production through the bidding up of prices, is an immeasurably larger permanent increase of gross product resulting from better application of skill and knowledge to local conditions.

#### HIGH PRICES FAIL TO STIMULATE PRODUCTION

"The production of sheep and wool in England was stationary until improvements in food and in breeding were wrought. It was the turnip and the new breeds of sheep which increased production of wool and not its high market price. The changes in cattle breeding both in regard to milk and beef tell the same story. The growth of these industries is a history of improved methods, each great change in the quantity produced being the consequence of antecedent stock improvements. These lessons America must take to heart if a remedy for our food shortage is to be found. High prices of food products will fail to stimulate an increase of their production. The remedy is in improved methods of production bringing prosperity to the farmer but also

pig iron, but through new processes of extracting ores and new economies of manufacture. The increase in the production of silver is a good example of the same tendency. The output of silver remained stable for centuries, little affected by prevailing high prices. What high prices could not do was accomplished by advancing chemical art. Increased production at lower prices followed.

"The history of every mineral product tells the same story. Stationary production is the accompaniment of high prices. We get increased production not in this way but by discovery, invention and increased knowledge, making the growth a result of these causes and not of price bidding. High prices is a distributive process creating profits, not a productive process augmenting production. Only when this is seen can an epoch of high prices like the present be understood. The urgency of war leads to vain attempts to speed up production. From them come high prices and inflation, but gross production is more often decreased than increased thereby."

A current experience of some illustrative value in this connection is brought out by figures published in the annual report to stockholders of the United States

<sup>1</sup>From a paper on "The Fallacy of Price Bidding" read by S. N. Patten at the recent annual meeting of the American Academy of Political Science. This important paper will appear in the July number of the *Annals of the Academy*.

<sup>2</sup>Patten, *supra* cit.

Steel Corporation for 1917. There is a falling off in tonnage of approximately 5 per cent.

|                                | 1917        | 1918        |
|--------------------------------|-------------|-------------|
| Iron ore mined .....           | 31,781,769  | 33,355,169  |
| Limestone quarried .....       | 6,494,917   | 7,023,474   |
| Coal mined .....               | 31,496,823  | 32,768,381  |
| Coke manufactured .....        | 17,461,675  | 18,901,962  |
| Blast furnace production ..... | 15,652,928  | 17,607,637  |
| Steel ingot production .....   | 20,285,061  | 20,910,589  |
| Rolled steel products .....    | 14,942,911  | 15,460,792  |
| Total .....                    | 138,116,084 | 146,028,004 |

The lack of correspondence between rising market values and volume of product is well illustrated by Table I. In the case of agricultural products, fortuitous and incalculable elements, such as varying weather conditions, have had an important effect. But the figures still have appreciable value.

#### THE ENDLESS CHAIN IN PRICE-BIDDING

A significant cause of the failure of price-bidding inflation to yield corresponding expansion in gross product lies in the fact that the bidding up tendency speedily extends to labor and intermediate goods which are in turn the products of labor. The wished-for harvest is great; and laborers are few. Immigration has virtually ceased. Our labor supply has become a fixed quantity and as successive military drafts make necessary inroads, the labor force will doubtless show an absolute decrease. Under these conditions, unrestricted price-bidding for essential commodities will merely raise market prices. These will be reflected in turn in expanded wage costs and inflated prices for machinery and related equipment, which are in turn labor products. The outcome is an alteration in distributive or income results without even approximate ratio of increase in volume of product. Profits mount amazingly in war-stimulated industries; labor moves toward such industries at rapidly advancing wage rates; non-transformable industries, not essential to the purposes of war, decline in material and financial productiveness. Price-bidding has caused a shifting of activities, an increase in market values; but aggregate product has diminished. The lure of advancing profits resulting from the raising of price margins yields no generally desirable social results. Profit is not product, and profit can serve as an incentive to product only when enlarged or better organized or more efficient labor force can be applied to tasks in hand. During the past year there has been no enlargement on better organization or demonstrable increase in the efficiency of labor. A reverse experience is the regrettable fact.

There has been no lack of price-bidding for the services of labor. With war industries setting the pace, wage rates have shown unprecedented advance. The following rates per hour are illustrative of minimum wage standards now prevailing in shipyards. These rates are for an eight-hour day, with time and a half for over-time, and double time for Sundays and holidays:

|                                         | Rate per Hour |
|-----------------------------------------|---------------|
| Anaesthetists .....                     | \$0 87 1/2    |
| Hammer and machine forgers, heavy ..... | 1 35          |
| Bolt makers .....                       | .72 1/2       |
| Electric welders .....                  | .65           |
| Boiler makers .....                     | .70           |
| Erecting leaders .....                  | .70           |
| Drillers .....                          | .55           |
| Chippers and calkers .....              | .70           |
| Painters and polishers .....            | .60           |
| Laborers and helpers, from .....        | 40 to 46      |

Changes in wage distribution between 1915 and 1917 strikingly emphasize the upward trend of wages.

Massachusetts figures, drawn from returns made by workers in whose cases compensation for industrial injuries was awarded, are quite illustrative:

| Weekly Wage Group  | 1915<br>Per Cent | 1916<br>Per Cent | 1917<br>Per Cent |
|--------------------|------------------|------------------|------------------|
| Under \$10 .....   | 26 41            | 15 64            | 7 92             |
| 10.01-15 .....     | 46 39            | 46 98            | 21 02            |
| 15.01-20 .....     | 18 24            | 24 60            | 37 53            |
| 20.01-25 .....     | 6 30             | 4 26             | 18 35            |
| Over \$25 .....    | 2 66             | 3 52             | 15 18            |
| Average wage ..... | 13 13            | 14 53            | 18 39            |

It will be noted from these figures that in 1915 only 2.66 per cent of the workers received a wage in excess of \$25 per week; in 1916, 3.52 per cent; in 1917, 15.18 per cent. At the same time, the percentage of those earning less than \$10 per week declined from 26.41 in 1915 to 7.92 in 1917.

The effect on wages of the expansion of munitions manufacture is well indicated by the following figures of a well-known New Jersey plant.

|                           | Male Workers Over 16 Years of Age<br>Per Cent of Total   |       |       |       |
|---------------------------|----------------------------------------------------------|-------|-------|-------|
|                           | 1916                                                     | 1917  | 1916  | 1917  |
| Under \$15 .....          | 812                                                      | 89    | 36 4  | 2 5   |
| \$15 but under \$20 ..... | 815                                                      | 450   | 36 5  | 12 6  |
| \$20 and over .....       | 605                                                      | 3,023 | 27 1  | 84 9  |
| Total .....               | 2,232                                                    | 3,562 | 100 0 | 100 0 |
|                           | Female Workers Over 16 Years of Age<br>Per Cent of Total |       |       |       |
|                           | 1916                                                     | 1917  | 1916  | 1917  |
| Under \$12 .....          | 1,412                                                    | 1,245 | 100 0 | 45 8  |
| \$12 and over .....       | ...                                                      | 1,477 | ...   | 54 2  |
| Total .....               | 1,412                                                    | 2,722 | 100 0 | 100 0 |

It will be noted that in the case of male workers only 27.1 per cent earned \$20 or more per week in 1916. In 1917, 84.9 per cent earned \$20 or more. In the case of the female workers, none earned as much as \$12 per week in 1916. In 1917, 54.2 per cent were earning \$12 or more.

#### LABOR DEMORALIZED BY PRICE-BIDDING

No one endowed with adequate fellow-feeling would suggest that workers are not justified in making their demands as urgent as possible and in gaining every advantage from the present labor shortage that may honestly be turned to account. They have at least as fitting a claim as have other classes which are profiting by the war. Their necessities are greater, and their real gains in the goods that money will buy will in any case not be appreciable. There is a vast difference, however, between a justification of their effort to alter the distribution of income and the maintenance of a view that increased wages will enlarge industrial output. The Director General of Railways is about to put into force wage increases for railway workers which will aggregate several hundred million dollars. Will the workers' contribution to transport services show any corresponding augmentation? The answer is reflected in the increase of freight and transportation charges already in process of application. There will be no change in output of railway services attributable to wage increases. The same is true of the wage-bidding of munition and ship-building plants. Labor has been demoralized. Workers have become bargain hunters. Labor turnover has assumed unwanted proportions. A round of visits to ship-building plants made nine weeks ago showed many groups of workers vigorously discussing wage-rates and earnings, rather than bolting ship-plates or driving rivets. Superintendents and bosses were exercised and often incensed, but helpless. Governmentally standardized wage-rates have since afforded a measure of improvement, and

more rigorous control over the distribution and migration of workers will sooner or later do much more; but what has been done cannot be undone.

"It is the conditions which surround the worker that determine his efficiency. Improvements in health, sanitation, housing and other elements in the home environment have a bearing on industrial efficiency and by them are the betterments of the worker to be measured. Price-bidding thwarts what the local environment stimulates. It leads to dissatisfaction, dissipation and to misplaced energy. Its lesson is therefore the same as that of other price bidding whether in food products or in raw material. There is an increase of waste but not of product. Increased production comes from an organization of the hitherto unused or partially used elements of the working population. It is easier to raise lower groups to a higher efficiency than to divert well-paid workers from one occupation to another. A new industry in war time or in peace should build up its own labor force out of the misplaced or partially used workers. A worker's training can be readily acquired if the discipline and oversight is what it should be. The increase of production mainly depends on moving those below the normal standard of living up to this standard and not on giving more to those above this standard.

"Why the moving of workers up to a decent standard of living is a productive problem is clearly shown by the rejection of recruits in the recent draft. Above 35 per cent of the recruits were rejected, of which 60 per cent were for removable causes. It is also estimated on the basis of these facts that three-fifths of those between 31 and 45 are physically unfit for military duty. A half of the working population are thus below the normal level of physical vigor and of these, more than a half are disabled from preventable causes. When we realize the reduction in labor efficiency which these defects cause, we can readily see what their removal means. Industry would gain both in gross and net product if the cost of removal were assessed against it. This shows what a living wage with proper care of health, sanitation and housing would do. The interest of every portion of society is promoted thereby. The sacrifices of the poor add no one. They reduce both the gross and net return of industry.

#### HOW REALLY TO BENEFIT LABOR

"The way to benefit the higher class of laborers is not by higher wages but by increased inducement to save. Price bidding makes spenders and increases both extravagance and waste. Saving aids production and modifies workers in ways which increase production. The man who spends all he earns, be he a worker or a salaried man, is dependent on a capitalist class, and to increase production will in the long run be the victim of the social order his defects make necessary. It is higher rates of interest which the uplift of the worker demands. He needs motives to check spending and not a freedom to indulge his caprice."<sup>3</sup>

Much can also be done by the working out of a comprehensive policy of labor distribution through a coördinated system of labor exchanges. The present indiscriminate practice of drawing workers from their present attachments by peripatetic employment agents and by promiscuous advertising cannot be too strongly

condemned. A centralized system of registration with local agencies to estimate local needs and to facilitate the distribution of workers would afford a vast improvement over prevailing anarchical conditions. A sample of what might be done in this direction has been afforded by English experience and by recent experimentation in the State of Ohio.<sup>4</sup>

A marked shortcoming of the competitive price-regulating régime, often unrecognized, is the wasteful duplication and lack of unity in the use of large-scale facilities of production and marketing. It is a well-recognized fact that large-scale producing units, involving the use of highly specialized and highly expensive equipment, tend to become cut-throat in their competitive practices. Some sort of common arrangement with regard to marketing practices is an inevitable outcome. But, short of actual combination, these arrangements, though financially salutary, have contributed little to the attaining of operating unity, so essential to the elimination of waste. Pools have been effective as dividend savers, but useless in directly promoting growth of product and of services from coördinated management. Railroad history affords striking illustrations of this situation. Railroad pools were never formed for any other purpose than control over rates. The carriers discovered through sad experience that competitive rate-warfare was disastrous to strong and weak roads alike. The pool was a resulting device to prevent rate-cutting by apportionment of competitive traffic or of the receipts from such traffic among the roads concerned. Pools were declared illegal by the courts, but subsequently established understandings have been no less effective. It is no fortuitous circumstance that rates between competitive points are the same on rival roads with equal facilities, nor is it mere chance that rate increases are simultaneously announced by rival lines. Strictly viewed, these agreements may have been illegal; but they have been winked at because public authority has had power to prevent arbitrary increases.

#### WASTE THROUGH LACK OF UNITY

But the mere existence of pools and agreements operating under public sanction did not produce operating unity. To the contrary, examples of uncoördinated organization and operation are legion. In the New York district there is an extreme example of wastefully competitive terminal facilities, where topographical conditions would permit high operating efficiency. Engineering experts have pointed out again and again how certain belt and marginal railroads with bridges or tunnels would bring the terminal facilities of the harbor into a great flexible unit. But the monopoly of a single road has forced continued reliance on scattered, inadequate and wasteful arrangements.

Some years ago the Wabash Railroad began to build a subsidiary line into Pittsburgh. The money spent by the Wabash in furthering its plans added to that spent by the Pennsylvania in opposing them would have paid for the construction of an adequate Pittsburgh terminal. Of what inestimable value such a terminal would have been during the past two years of traffic congestion in Pittsburgh!

<sup>3</sup>Cf. of two articles by W. M. Lelerson in *The Survey* for March 30 and April 20, 1918. Also Leschier: "A Clearing-House for Labor," *Atlantic Monthly*, June, 1918.

<sup>4</sup>Patten, *supra cit.*

In Chicago twenty-five trunk lines enter the city. These have twice the trackage requisite for the handling of freight under a unified terminal system. Every day some 2000 tons of through freight, in less than car-load lots, are hauled by truck from inbound to outbound stations. In fact, almost the whole of Chicago's terminal system is obsolete and needlessly inefficient. Admirable plans of reorganizations have been worked out; but these have been fruitless because individual companies will not surrender strategical advantages acquired in the early days of their development. One cannot blame the managers of the roads. They have but followed the competitive creed under which our railroads have developed. Within the past year, under the stress of war, there were efforts at coordination, but these could not be made completely effective under private management. The Government has taken over the roads, in all likelihood for a period of years. As President Wilson has said: "The group of railway executives who are charged with the task of actual coordination and general direction performed their difficult tasks with patriotic zeal and marked ability, as was to have been expected, and did, I believe, everything it was possible for them to do in the circumstances. If I have taken the task out of their hands, it has not been because of any dereliction of failure on their part, but only because there were some things which the Government can do and private management cannot."

What is true of the railroads in war times is measurably true of other complicated, large-scale, competitive units in other fields of production and distribution.

The considerations thus far urged have received more or less conscious recognition in the practices and policies of the nations at war. Aside from our own, we know most about the British experience.<sup>5</sup>

#### WAR-TIME EXPERIENCE OF GREAT BRITAIN

Starting with a strong predilection for *laissez faire*, British control of industry has passed through three phases. The first, extending over a period of less than a year, was one of tentative action, looking only toward obvious measures of self-protection. The second, lasting for some seventeen or eighteen months, was a period of determined regulation. The Government's chief concern was that of increasing the output of munitions of war, of securing supplies for the army at prices below those of the market, and of regulating shipping. The third phase, beginning at the end of 1916, has been one of stringent control, governmental regulation of the production, distribution and consumption of food being its most prominent feature. "The doctrine of *laissez faire*, still respected in 1914, had by the end of 1917 passed into at least temporary oblivion."

Control over the prices and distribution of essential metals are typical of British practices. Through the medium of this control, the Ministry of Munitions achieved triumphant results during the first year of its activity.<sup>6</sup> This involved interferences with the

normal course of trade which went beyond even the control of employers' profits and the restriction of trade unions' liberties and practices. Raw materials were controlled throughout the processes of conversion into munitions. "The great lesson of the early months of the War," said Mr. Montagu in an August, 1916, speech before Parliament, "was that munitions cannot be obtained merely by ordering. You have got to see that the man who takes your orders has the plant and the labor; you have got to follow up the work process by process; you have got to provide from the beginning to the end everything that is necessary. That is the cardinal principle of the Munitions Department."

Following this principle, the Government early turned its attention to the supplies and prices of iron, steel and copper. During 1915 market quotations for these metals had advanced rapidly. Conditions in the import trade were largely responsible. American supplies had been so largely diverted by home demand that semi-steel could scarcely be obtained. Freight rates, too, rose from 15s. to 65s. per ton. As a result, the price of bar-steel, used in shell making, advanced from £7 15s. in January, 1915, to £11 in July, and to £14 in December. American billets, which early in the war brought \$5 per ton c.i.f., so far as available at the end of the year, sold for £10 10s. Hematite rose from 71s. a ton in January to 115s. in December. The increased value of skilled labor needed to transform forge pig into bar pig was reflected in a changed price ratio of from 1 to 2, to 1 to 3.<sup>7</sup>

#### GOVERNMENT FIXES MAXIMUM PRICES

This was the status of price movements in January, 1916, when the Government resolved to prevent further appreciable rise in prices. Maximum prices for all finished iron and steel goods were fixed. These were revised in April and again in November. The following quotations will illustrate the stabilizing effect of these measures:

|                              | January, 1915 | January, 1916 | December, 1916 |
|------------------------------|---------------|---------------|----------------|
| Steelship plates, per ton... | £8            | £11 10s       | £11 10s        |
| Iron ship plates ...         | £7 15s        | £11           | £11 10s        |
| Steel sheets (singles)....   | £8 5s         | £13 10s       | £14            |
| Common iron bars ...         | £8            | £10 10s       | £10 15s        |
| Heavy steel rails ...        | £6 7s 6d      | £11           | £10 17s 6d     |

At the end of February maximum rates were set for pig-iron below those ruling in the market. On Feb. 22, Cleveland No. 3 sold in Glasgow for 98s. 6d.; on the following day there were rumors that the Government would insist on transactions at 82s. 6d. The market broke forthwith, and 2500 tons were sold at 87s. 6d. Private transactions continued for some weeks, but gradually waned until the metal exchanges in London and Glasgow lapsed into lifelessness.

The Government next took steps to stabilize the price of iron ore, of which in 1916 some 6½ million tons were imported. But guarantees were given, both in freight rates and in ore prices, to meet any differences that might arise between fixed prices and actual costs. Precautionary notice was served that the maximum prices for steel and iron were based upon abnormal costs and conditions then prevailing, and must not be assumed to indicate differences in relative values obtaining in the several districts before the war, or which might obtain again after the war.

<sup>5</sup>My illustrations of railway conditions have been drawn from one of a series of five striking articles, by T. W. Van Meter, now running in *The Traffic World*. The article in the number for May 11, 1918, affords a significant discussion of the faults of private management.

<sup>6</sup>An excellent discussion of the British experience will be found in Gray, H. L., "War-Time Control of Industry," *The Macmillan Co.*, 1918.

<sup>7</sup>Gray, *supra* cit.

<sup>8</sup>My facts are drawn from Gray, *supra* cit.

On Feb. 29, 1916, the Government forbade speculative trading. Thereafter, dealings in iron, steel, copper, zinc and certain other metals became unlawful except in cases of direct transfer by owner to consumer or consumer's agent. During January and February the prices of copper, lead and iron, owing largely to speculative dealings, had reached previously unprecedented war levels. Copper was higher than since 1907, and the other metals had broken previous records. Compared with 1913, the quotations were:

|                | Highest Price<br>Since the War | Highest Price<br>in 1913 | Lowest Price<br>in 1913 |
|----------------|--------------------------------|--------------------------|-------------------------|
| Copper per ton | £108                           | £78                      | £62                     |
| Lead .....     | £35                            | £22                      | £15                     |
| Spelter .....  | £120                           | £27                      | £20                     |
| Iron .....     | 98s.                           | 70s. 6d.                 | 48s. 6d.                |

Under the new prescriptions iron was to be sold at 82s. 6d. Copper was imported, so that its price could not be fixed. There have since been marked fluctuations in copper prices; but, at least, profits of home speculators were eliminated.

#### ECONOMY AND EFFICIENCY IN THE USE OF MATERIALS

The next step was that of securing economy and efficiency in the use of metals. Restrictions were first put upon the exportation of iron and steel to neutrals. As early as July, 1915, the exportation of high-speed steel had been prohibited, except under license; and thenceforth only a small part of the licenses asked for were granted. Early in 1916 neutral markets were further closed, except through occasional grant of permits to adjust the balance of trade. Of this the shipment of steel rails to South America is an example.

As between home consumers, priority regulations ruled. In the beginning they affected only controlled establishments; but by March, 1917, more than 90,000 firms had been brought within their scope. With an underlying purpose of securing essential supplies to industries in the order of war-time importance, they provided, relative to steel and copper wire, that no order (other than for shell-discard quality) should be accepted by a manufacturer except with Government approval. Such approval was safeguarded by detailed regulations; and each week manufacturers were required to make full returns to the Director of Steel Production of all steel manufactured or delivered.

#### PRIORITY PRINCIPLE APPLIED TO LABOR

The principle of priority in industrial work was next extended to contracts for the employment of labor under a Restricted Occupations Order. Industries not conducive to military ends were by these means forced to the wall.

"By the spring of 1917 the Government was in pretty complete control of the vast business of manufacturing munitions, especially in control of the supply of iron and steel. Its first endeavor had been to enlist in its service private engineering and shipbuilding firms and to attempt the mobilization of labor; it had ended by fixing the price of iron and steel by determining the allotment of these and other metals to the manufacturer and by directing the supply of labor into essential trades. It had, in short, extended its control from producer to consumer, undertaking almost everything except the appropriation of the mines and the works."

Judged by any standard of the adapting of means to

ends, British experimentation has been a success. Employers have complained little except in non-essential trades. Some would have welcomed a more liberal export policy in order to share in the higher prices of the world market. But essential industries have been crowded with orders, and business has been continuously active. A liberal profit margin has prevailed, so that little friction has developed between manufacturers and the Government. And most of all, ships, munitions and other war essentials have been turned out in growing volume.

#### PRICE-FIXING GOOD ECONOMY

Great Britain has been impelled further toward state control of industry than the United States has thus far gone. We are still much more largely reliant than they on the voluntary cooperation of citizens. Only time can tell how far we shall go in their direction. But in any case, governmental judgment is quite likely to coincide with that recently expressed in the columns of a popular weekly:\*

"Of course price fixing curtails production. With more pinches there will probably be more criticism of it on that ground. When coal prices were soaring, without a check in sight, mines that could not be worked profitably at anything like normal prices were opened up. Almost any sort of contrivance in which iron could be made found a profit in operating when that commodity sold round seventy dollars a ton. When the Government fixed the price at thirty-three dollars resurrected and improvised furnaces had to shut down.

"But price-fixing, though it does cut out a certain amount of extravagantly dear production, is good economy. The country is in a sounder position with somewhat less iron at thirty-three dollars a ton than it would have been with a somewhat greater output at seventy dollars. The increased supply of either coal or iron would have been relatively small. In the case of coal the real famine was in transportation rather than in fuel." An increased supply at the mines would have done no good when cars were not available to haul it. The iron pinch is quite as much a lack of transportation and labor as of metal. The stock of materials will answer if it is handled to good advantage.

"The objections to abnormal prices are psychological and political as well as economic. Few things in this sordid world are more likely to put a nation out of tune than having to pay double or treble the accustomed price for a necessary article of universal use. At best, high prices are bound to be a sufficient affliction during the war. Limiting the price of certain basic articles by Government action would be justified as a political measure, even if it could be shown, by some miraculously comprehensive calculation, that there was no net economic gain in it."

Columbia University,  
New York City.

Exports of gold for April 1918 were 3560 thousand dollars with imports exceeding 2745 thousand dollars, leaving a balance of gold movement against us in excess of 814 thousand dollars.

# Flotation Apparatus, Their Design and Operation

## Classification and Summary of the Types of Machines—Capacity, Air and Power Consumption—Cost of Equipment

BY A. W. FAHRENWALD

IN THE last three years great strides have been made in mechanical appliances for the purpose of concentrating ores by the flotation process. Many patents have been taken out for such devices, and a large number of them have been put into operating mills and are giving satisfactory results; others have not reached such wide application.

Before proceeding to a discussion of the various types of apparatus used in the process, it will be necessary to classify them. The classification which will follow does not include types that have served as a link in the chain of designs leading to the present developed system. Neither will it include the so-called "film" flotation processes, as their field of usefulness seems to be quite limited, and since most of these processes or methods are expensive because of the limited amount of mineral that can be floated at one time on the surface film of water. They can not handle finely divided slime, yet it is certain that the present popularity of "froth flotation" depends on its success in the treatment of ore-slime. For this reason it is easily seen that the application of machines using the "skin" or "film" principle is limited. It is noteworthy, however, that McQuisten's method is at present in use for the treatment of table middlings at the Morning Mill, at Mullen, Idaho. Barite and siderite are there present as gangue minerals in a middling containing zinc and lead sulphides. As these heavy gangue minerals can not be separated by gravity methods of concentration, the alternative of grinding them fine enough for froth flotation or of treating them by film flotation has so far enabled the latter to survive the competition of froth flotation. At the ore-testing plant of H. E. Wood, of Denver, a film flotation machine is also removing molybdenite from a low-grade ore. There is little doubt, however, that froth flotation could be used for every separation of minerals that is now being accomplished by film flotation, providing the material were ground fine enough.

The following classification, then, includes apparatus most widely used in practice:

- I. Straight mechanical frothing machines.
  1. "Minerals Separation" type of machine.
  2. Janney machine.
- II. Mechanical-air frothing machines.
  1. Minerals Separation sub-aeration machine.
  2. Janney mechanical-air machine.
  3. Kollberg-Kraut (K. & K.) machine.
- III. Pneumatic frothing machines.
  1. The Callow pneumatic machine.
  2. Flinn-Towne machine.
  3. Cole-Bergman machine.
  4. Inspiration machine.

5. Launder machine (Snyder).

IV. Gravity frothing machines.

1. So-called "cascade" or "hydraulic" flotation machines.

The above classification is based on the fact that all machines recover the mineral sought by forming a froth or foam. Without the formation of a froth, the physics of which has been discussed frequently in the technical press,<sup>1</sup> no mineral will be concentrated. In the important froth flotation processes the mineral-carrying froth is produced by either beating air into the pulp by mechanical means or by injecting it in the form of small bubbles.

### I. STRAIGHT MECHANICAL FROTHING MACHINES

Machines of this class probably were the first to receive practical application. They advanced regularly

FIG. 1.—THE MINERALS SEPARATION MACHINE

in design, reaching a fairly high state of perfection before the pneumatic type was introduced.

1. The "Minerals Separation" type owes its present state of development and perfection to the metallurgical staff of Minerals Separation, Ltd., among whom Froment, Cattermole, Picard, Sulman, Ballot, Nutter and Hoover deserve special mention. The ideas of many others have also been taken over by this company.

The Minerals Separation machine used at the present time will be described best by reference to the installation at the Washoe Reduction Works of the Anaconda Copper Company.<sup>2</sup> Fig. 1 shows the machine at various angles.

The feed is introduced into the first agitation box at the motor end of the machine, M. From this box

<sup>1</sup>See "Flotation in the Coeur d'Alenes," C. T. Rice, *Engineering and Mining Journal*, Vol. 105, p. 709 (Apr. 20, 1918).

<sup>2</sup>"On the Molecular Physics of Ore Flotation," Coghill and Wright, *This Journal*, June 1, 1918.

<sup>3</sup>"Flotation Concentration at Anaconda," *Bull. A. I. M. E.*, March, 1916.

it passes to a second box through an opening O in the partition, as shown in the elevation. From this second agitation compartment the pulp passes into the first spitzkasten S, where the first concentrate froth is formed and removed by means of a paddle. The pulp remaining passes through a pipe P, the inlet to which is controlled by a valve stem V, to the third agitating box A. From this agitating box the pulp

FIG. 2.—JANNEY MECHANICAL FLOTATION MACHINE

passes through the second spitzkasten, and so on through the machine until the pulp is introduced into a fourteenth or last spitzkasten K. The discharge from the last spitzkasten leaves the machine as tailings. The first four to seven spitzkasten make finished concentrates and the remaining ones make middlings that are returned to the system. The drawings show a double machine—each machine however, being run as a separate unit. The line shaft is driven by a 150-hp. motor at a speed of 385 r.p.m. and requires about 100 hp. under load. The vertical shafts carrying the impellers revolve at a speed of 225 r.p.m. The impellers have four blades placed at right angles and inclined 45° to the vertical, made of gun metal, 18 in. in diameter, giving a peripheral speed of 1,060 feet per minute. Each pair of impellers is so arranged that they revolve in opposite directions, which tends to balance the side thrust on the line shaft. The bevel gears that drive the impeller shaft are cut-steel and run in grease. The impeller shaft is supported both vertically and horizontally by ball bearings.

The machines are made of California redwood; the agitator boxes are further lined with hard maple extending about 18 in. from the bottom of the box.

Each machine makes three products: concentrate, which goes to the dewatering division; middling, returned to the head of the machine; and tailing, to waste. Concentrate is taken from the first three to five spitzkasten and middling from the last nine to eleven.

**2. Janney Machine.** Fig. 2 shows the mechanical machine,<sup>4</sup> which is constructed of cast iron, with the exception of the spitzkasten. The whole machine is

attached to a main casting C which sets on a foundation of concrete or timber T in the middle (Fig. 2). Inside this main casting is a liner casting L which takes the wear, and which is baffled on the lower portion so that the pulp receives a very violent agitation. Above the main casting sets a top liner B and a support for the motor. A shaft S, on which there are two impellers, is screwed to the lower end of the motor shaft, and turns with the rotor at a speed of about 570 r.p.m. It is made heavy enough, and the bearings in the motor are of sufficient size, so that there is but little vibration. The impellers on these shafts are of two sizes; the lower one is the smaller and revolves inside the baffle on the liner, while the upper one revolves just above the baffles, and throws the pulp up and out into the spitzkasten P on either side of the agitating chamber.

The Janney machines are of the double spitzkasten type, i.e., each agitator serves two spitzkasten. On each side of the agitating chamber there are two open-ended circulating pipes R, which lead from the bottom of the spitzkasten up and into the same agitating chamber. Each spitzkasten is divided by a baffle or partition, which prevents the pulp from flowing through the series of machines without passing through the agitating chambers. Any desired height of pulp-level is maintained by regulating a gate between the spitzkasten with a hand wheel W, then the rate of flow from "spitz to spitz" depends entirely upon the volume of feed entering the machine. The amount of pulp circulating in each unit machine builds up to its capacity, and then remains constant, due to the regulating gate between the spitzkasten.

The circulating feature of the machine allows the pulp to be treated many times. When the pulp is thrown out from the agitating compartment into the

FIG. 3.—MINERALS SEPARATION SUB-AERATION TYPE OF FLOTATION MACHINE

spitzkasten a froth is produced. A froth remover F driven by a small motor installed at one end of the row of machines removes it as formed.

A typical installation of Janney mechanical frothing machines (known as a multiple-series arrangement), consists of two mixers or "emulsifiers" and fifteen Janney mechanical machines in a row. In such an installation the feed is divided among the first five cells. The tailing of each of these five cells enters the sixth cell and from the sixth cell it advances from "spitz to spitz." The slope required is 1½ inches per foot.

This machine is adapted to the treatment of a classified feed or of ores of high mineral content, and is

<sup>4</sup>Catalog, Stimpson Equipment Co., Salt Lake City, Utah.

especially adapted for treatment of low-grade concentrate produced on tables or vanners. The feed should all pass 40-mesh for best results, while the percentage of solids in the feed should range from 20 to 23 per cent.

A feature of this machine distinct from most other mechanical agitation machines lies in the individual motor drive for each agitator compartment. This arrangement is accompanied by the many advantages accruing to any individual-motor-driven machine, but its high first cost would usually be beyond the means of the small operator.

## II. MECHANICAL-AIR FROTHING MACHINES

In most cases these machines have been introduced since the debut of the pneumatic system of floating minerals. The object in this machine is to combine the advantages of both injected air and mechanical agitation. This combination increases the chance that any particle will be caught in traveling a given distance.

1. **The Minerals Separation Sub-aeration Machine.** As seen from the illustration,<sup>5</sup> Fig. 3, pressure air is admitted to the pulp conduits P leading from the spitzkasten to the agitation compartment next in succession, in order to make this air available in lifting mineral to the top of the spitzkasten where it can be skimmed off. The agitating compartments are closed at the top by covers C set on an incline in such a way that the air rising to the top in the agitating compartment is conducted to the spitzkasten S, being thereby utilized for the purpose of carrying the mineral values, as noted.

The above construction led to a design of greater simplicity, known as the "Hebbard" type of minerals separation machine,<sup>6</sup> which consists of a long rectangular tank without any partitions, in which a number of agitators revolve, while air is injected under each impeller. In order to limit the agitation to the lower part of the machine, and to provide an area of comparative quiet in the upper part, a system of baffles is arranged above the agitators. As a consequence the froth is given a chance to separate in the upper portion of the rectangular tank, and flows off on both sides into lengthwise launders provided for the purpose. This, it will be seen, is a phase of operation similar to that of pneumatic machines where the froth, formed in the one compartment, flows over into launders.

This machine no doubt marks an important step<sup>7</sup> in

the development of the Minerals Separation flotation system. The simplicity of the machine is remarkable and does away with the bulky spitzkasten and the mechanical device for removing the froth. The floor room required for the machine is thus reduced to a minimum which is an important point in mill practice.

2. **Janney Mechanical-Air Machine.** The mechanical agitation in this machine<sup>8</sup> is obtained in the same manner as in the Janney straight mechanical machine. There is a continuous circulation of pulp through the mixing chamber and over the air mat. From the emulsifier E, Fig. 4, the pulp and oil, thoroughly beaten together, pass to the agitating chamber A of the first machine through a pipe P. From here it overflows continuously into the spitzkasten S. The froth flows over the gate G, while the un-retained pulp flows over the gate B, which controls the height of pulp in the "spitz." From here the pulp flows through a pipe, R, to machine No. 2, and so on down through the series.

The bottom D of the spitzkasten is a cast-iron pan, divided into three compartments, the whole being covered by four layers of cross-stitch palma twill. The pan is divided into three compartments so the air may be regulated to meet the varying hydraulic head

FIG. 4.—JANNEY MECHANICAL-AIR MACHINE AND EMULSIFIER.

within the spitzkasten, as a pressure of from four to five pounds is required.

These machines may be installed end to end, or side by side, usually in a series of one mixer, or emulsifier, and five flotation cells. The latter arrangement is used in small plants, as it is more compact: the floor space required is approximately 5 by 16 feet per unit, with a drop of 3 feet between cells. For the end-to-end arrangement the floor space required is approximately 4 by 16 feet, with a drop of 3 feet between cells.

3. **The Kollberg-Kraut machine** is a complete unit,

<sup>5</sup>Bull. A. I. M. E., Sept., 1916.

<sup>6</sup>Ibid., p. 1644

<sup>7</sup>As recorded by Laist and Wiggin in an article, "Flotation Concentration at Anaconda, Mont.," Bull. A. I. M. E., Sept., 1916, p. 559, this machine was a failure on account of too much disturbance in the upper part of the machine for the proper removal of froth. They do not say whether the top position was baffled or not.

<sup>8</sup>Catalog, Stimpson Equipment Co., Salt Lake City, Utah.

requiring no blower, air compressor, or pre-agitation. See Fig. 5, which shows details of this machine as used at the Burro Mountain Mill,<sup>9</sup> Tyrone, New Mexico.

The feed enters at one end of the machine through a five-inch feed pipe F, the tailings being discharged at the opposite end through a four-inch pipe T, while

FIG. 5.—DETAILS OF THE FLOTATION MACHINE AT THE BURRO MOUNTAIN MILL.

the concentrate is discharged over the lip M of the frothing chamber C into a suitable launder. An adjustable level-control device is provided which maintains the proper level of pulp in the machine, which in return furnishes the correct height of the bubble column in the frothing chamber.

The machine consists of a cylindrical housing about 10 ft long and 30 inches in diameter. Inside the aëration chamber A is located a rotor R which consists of a  $3\frac{7}{16}$ -inch steel shaft S, on which is mounted four cast-iron spiders P for carrying the lagging and riffles L of the rotor. The lagging forming the periphery of the rotor is so spaced as to leave a  $\frac{1}{4}$ -inch opening between each piece. There are 16 of these pieces and each is provided with four hard-wood or steel riffles, which run the entire length of the rotor. The rotor revolves at 180 r.p.m. and has a clearance of three-eighths inch between its outside periphery and the inside surface of the aëration chamber.

The rotor shaft passes through the two end plates of the machine by means of two air ducts, of ample size

to furnish all the air necessary to thoroughly aërate the pulp as it is revolved. There is no leakage of air through these air ducts, but a continuous influx of air from the atmosphere which is discharged by centrifugal force through the air slots between each of the 16 pieces of riffled lagging forming the periphery of the rotor. It immediately comes in contact with a thin film of pulp which has been circulated by the rotor, and the revolving pulp is thoroughly aërated in the space between the outside periphery of the rotor and the inside surface of the aëration chamber.

The housing can be removed for replacing the riffles, which last from four to six months. The floor space required by this machine is 4 feet by 14 feet, and from 6 to 8 hp. is required to operate it.

### III. PNEUMATIC FLOTATION MACHINES

The first application of pneumatic flotation for the treatment of ore was made at the mill of the National Copper Company at Mullen, Idaho, which was designed and constructed by J. M. Callow.<sup>10</sup> Construction was started on Aug. 14, 1913, and the plant went into operation about April 10, 1914. The Callow pneumatic system was a success from the start, and it is interesting to note that it had been so thoroughly thought out in its initial design that during three years of operation little or no change has been made. Other machines operating on the pneumatic principle, in general, have also been successful.

1. The Callow Pneumatic Machine. Fig. 6 illustrates the various elements composing the Callow process in general.

In the mixer A, operated by compressed air, oil, air and water are mixed and emulsified; the same type of

FIG. 6.—CALLOW PNEUMATIC FLOTATION PROCESS

apparatus (Pachuca tank) is in common use in cyanide works. In case the oil or frothing agent can be fed into the crushing machine or tube-mill, this mixer can

<sup>9</sup>"The Burro Mountain Concentrator," by L. C. Blickensderfer, *Eng. and Min. Journal*, Jan. 14, 1917.

<sup>10</sup>"Notes on Flotation," Historical sketch, *Bull. A. I. M. E.*, No. 108, p. 2321-2339, Dec., 1915. "Callow Pneumatic Flotation Process," *3rd, and Chem. Engrg.*, v. 13, p. 571-572, Sept. 1, 1915; *Eng. and Min. Jour.*, v. 100, p. 919-923, Dec. 4, 1915.

be dispensed with, the tube-mill discharging direct into the separatory cell. It has been conclusively proved that agitation of the pulp, before subjecting it to the bubble column, is not necessary to successful flotation by the pneumatic method.

The initial or roughing cell B consists of a tank about 9 feet long over all, and 24 inches wide, with a bottom inclined at from 3 to 4 inches per foot, 20 inches deep at the shallow end and 45 inches deep at the other end. It may be built of either wood or steel, but wood construction is preferable.

Fig. 7, shows the cell in detail as used at Inspiration." The bottom of the tank consists of a porous medium made of four thicknesses of loosely woven canvas twill," properly supported by a backing of perforated metal to prevent its bulging under air pressure. Through this porous medium compressed air is forced by the blower E, Fig. 6. The space underneath this porous medium is subdivided into eight compartments, each connected by an individual pipe and

of the side gutters to the pump D (Fig. 6) and then to the cleaner cell C, of the same construction as the rougher. Usually one cleaner serves four roughers and operates under a slightly lower air pressure.

A given number of cells may be run either in parallel or in series without any sacrifice in capacity. On one ore the series-treatment gives a slightly cleaner tailing; on others it does not. Usually two cells in series is sufficient. In a heavily mineralized ore the series arrangement is a decided advantage, as the possibilities of any particle of mineral to escape are lessened.

2. **The Flinn-Towne Machine.** In Fig. 8 is seen a single cell of this type. It operates on the pneumatic principle, although the application is somewhat differ-

FIG. 7.—DETAILS OF CALLOW PNEUMATIC FLOTATION MACHINE

valve to the air main. By this means the pressure in each compartment can be regulated to correspond to the varying hydraulic head within the tank, and so discharge a uniform amount of air throughout the length of the tank. A pressure of from 4 to 5 pounds is generally used, each square foot of porous medium requiring from 3 to 10 cubic feet of free air per minute.

Each longitudinal edge of the tank is provided with a lip and an overflow gutter for the reception of froth to be discharged. The lower end of the tank is furnished with a spigot discharge fitted with a float-operated plug valve to maintain a uniform water-level within the tank and thus, in turn, maintain a uniform and constant discharge of froth under all varying conditions of feed incident to practical milling operations. The water-level may, of course, be varied, but is usually maintained at from 10 to 12 inches below the level of the overflow lip. The tailing is discharged through the spigot and the frothy concentrate is conveyed by means

ent from that of the Callow system. The cells are constructed in the shape of cylindrical tanks, 24 inches in diameter by 6 feet 6 inches in height, the bottoms of which are formed by the porous medium. The feed enters near the top and near the center of the cylinder D through an adjustable disc E, while the tailings leave the machine through a center hole F in the porous medium. The goose neck G, which extends up above the porous bottom, is for discharging the tailings; it also controls the height of pulp-level in the cell A. Sands that are too heavy to be carried up the goose neck may be drawn off through the pipe K. Through the pipe P, air under pressure enters the chamber C, and is injected into the pulp through a carborundum disc (canvas may also be used). The concentrate froth overflows around the circumference of the cell into the launder K.

It is evident that this cell would be limited in capacity on account of its round shape. If a large unit were built it would be bulky and also the distance the froth would travel to leave the machine would be too great for good work.

<sup>12</sup>This form of bottom was also first used by Callow and is the standard bottom used at present.

## IMPROVEMENT ON FLINNE TOWNE MACHINE

With this apparatus as a suggestion Messrs. Cole<sup>b</sup> and Bergman have designed an apparatus which is an

FIG. 8. FLINNE TOWNE MACHINE

Improvement on the Flinne Towne machine. It, however, embodies many of the principles of the latter.

(To be continued.)

## Gas Chemists of Bureau of Mines Transferred to War Department

By order of President Wilson dated June 29, 1918, all of the activities of the Government concerned with the investigation and manufacture of poison gas for war purposes were transferred on July 1 to the control of the War Department. The research work on this subject was begun some months ago under the direction of the Bureau of Mines which established a chemical section at the American University, Washington. In making the transfer, President Wilson acknowledges the excellent work done by the Bureau in establishing and maintaining this work, but states that a more efficient organization can be effected by concentrating all of the facilities for offensive and defensive gas operations under the newly organized Division of Gas Warfare. The gas experiment work is now under the direction of Major General William L. Sibert who was recently returned from France where he commanded the First Division of the regular army.

## Bibliography of Electric Furnace for Brass Melting

IN METALLURGICAL AND CHEMICAL ENGINEERING, June 1, 1918, page 533, H. W. Gillett and A. E. Rhoads presented an article on a rocking electric brass furnace. Owing to lack of space at that time the following bibliography was omitted:

## After-the-War Program of Vickers (Ltd.)

This firm is now establishing a market for sewing machines to be produced at one gun factory by the 1700 general service machine tools there available. A study of the proper reduction of waste has led to the installation of a plant for making wooden ware, which is to be rapidly expanded, and which will get its raw material from their shipyards even after they have been converted from the making of war ships to those for the mercantile marine. Another plant is to make automobile accessories. Vickers have also acquired the Bosche Magneto Works and partial control of the British Westinghouse Co.

## The Role of Complex Salts as Electrolytes in Plating and Refining Baths\*

BY REGINALD S. DEAN AND MING YI CHANG

IT HAS long been known that complex salts gave smoother and more adherent deposits than could be obtained from equivalent concentrations of simple salts. The reason for this as commonly given is that the deposit is the result of a secondary reaction, the metal being precipitated rather chemically than electrolytically; e.g., the silver from a potassium-silver cyanide solution is assumed to be deposited by the preliminary discharge of the potassium ion and subsequent deposition of the silver by the potassium formed. This explanation seems a bit forced since there is no *a priori* reason why the silver deposited by chemical action of the alkali metals should be

concentration of the ion being discharged, or, more generally, the greater the potential difference between the deposit and the bath the more nearly amorphous will be the deposit. He says:

"It is well known that silver and copper precipitate in a more nearly amorphous form from potassium cyanide solutions than from nitrate solutions. It is not a case of secondary deposition giving a good deposit as has sometimes been assumed because the decomposition voltages of the copper and silver cyanide solutions used in plating are lower than the decomposition voltage of the corresponding pure cyanide solution. As we can get a plating deposit of silver from a silver nitrate solution under suitable conditions it is obvious that there is no fundamental difference introduced by the formation of a complex salt. So far as the facts are known they can be formulated in the statement that the deposit is more finely crystalline the greater the potential difference between the metal and the solution."

The experimental evidence favors this theory for simple salts, at least so far as moderately large ion concentrations are concerned, as is shown by the accompanying pictures (Figs. 2, 3 and 4) of the

more smooth and adherent than the electrolytic deposit. Certainly the chemical deposit obtained by the replacement with iron is neither smooth nor adherent and that obtained with magnesium is even more coarsely crystalline, as shown by the photomicrograph in Fig. 1.

Glaser<sup>1</sup> has suggested that the beneficial action of the complex tartrates may be due in part to the reducing action of compounds formed from them during electrolysis. Bancroft thinks that this can possibly be extended to the effect of complex cyanides. Good deposits, however, may be obtained from many complex solutions which show no reducing action; e.g., the silver-ammonia complexes.

A third very interesting theory has been proposed by Bancroft.<sup>2</sup> It is based upon the fact that the crystallinity of a deposit decreases with decreasing

deposits obtained from hundredth, thousandth and ten-thousandth-normal solutions of silver nitrate. Whether this evidence can be extrapolated to solutions containing so little silver ion as the complex cyanides can not be definitely stated. An attempt to determine this experimentally was made, using violently stirred suspensions of silver oxide, chromate, chloride, thiocyanate and sulphide. In this way concentrations of silver ion comparable to that in the argenticyanide were maintained without the additional influence of a complex salt. The anode used was pure silver foil while the cathode was a highly polished copper strip. The current used was about 0.05 ampere and the voltage about 2.6; the electrode area was 2.5 square centimeters.

The deposit obtained from the silver oxide is shown in Fig. 5, and is seen to be somewhat more crystalline than that obtained from ten-thousandth-normal silver nitrate which is about what would be expected from the solubility of the silver oxide. We found it im-

\*Contribution from the Metallurgy Laboratory of the University of Pittsburgh. Experimental work from the thesis of M. Y. Chang.

<sup>1</sup>Glaser Zeit. f. Elektrochemie 7, 386 (1900)

<sup>2</sup>W. D. Bancroft, Journ. Phys. Chem. 9, 290 (1905)

possible to obtain a deposit from silver chromate or any of the less soluble salts even after the addition of enough potassium nitrate to make a 10 per cent solution. If, however, cyanide was added to any of these suspensions a solution was obtained which must obviously have been less concentrated in silver ion than

but the  $K^+$  ion, and the behavior of the latter is exactly what would be expected since the concentration of  $K^+$  ion is much larger in  $KAg(CN)_2$  than in a corresponding KCN solution, the extreme weight of the anion in the complex salt causing practically complete ionization.

Experiments to determine if the deposition of silver from a cyanide solution took place at the voltage which would be expected from the concentration of potassium ion were made. The apparatus employed was novel and will be described in some detail. It was essentially an adaptation of the Leeds and Northrup transition point instrument for the determination of decomposition voltage. The voltage was read on the difference couple galvanometer scale, the galvanometer being shunted directly across the cell with a graphite resistance in series. The graphite resistance is essential, and to insure constancy is best made in the manner developed by V. H. Gottschalk and R. S. Dean especially for this kind of work at the Missouri School of Mines. A plate of frosted glass or unglazed porcelain serves as a base and the lead-pencil line is drawn across it, the contacts being made with tin foil and screw clamps, and the whole placed in a dessicator over phosphorus pentoxide and the wires led in through a stopper. The use of a dessicator is much more satisfactory for preventing the absorption of water than any kind of wax or lacquer. The resistance necessary depends on the cell and electrodes used, but should be several megohms. In order to get readings which can be traced it is best to set the beam of light as far to the left as possible and then place about three volts across the galvanometer circuit and regulate the graphite resistance so as to get a readable value. The current is read by means of the thermocouple galvanometer and a 0.001-ohm shunt, the voltage across the shunt being balanced by the drum potentiometer. In the use of the apparatus

the current is gradually increased by means of a potentiometer and the voltage and current followed by the tracing pen. The connections and general construction of the apparatus are made clear by the photograph and

FIG. 7.—LEEDS AND NORTHROP TRANSITION-POINT APPARATUS SET UP FOR THE DETERMINATION OF DECOMPOSITION VOLTAGE

the suspension, but which, nevertheless, gave a good silver deposit (see Fig. 6).

It is not particularly surprising from the experimental point of view that no deposit is obtained from solutions so dilute in silver ion as silver chloride, since the decomposition voltage increases with the dilution, and at dilutions as great as that of insoluble salts exceeds the hydrogen decomposition point and hence the current efficiency drops practically to zero. But why do we obtain a deposit from a cyanide solution which certainly contains less silver ion than the chloride solution, since we have no reason to believe that the decomposition point of an ion depends on anything but the concentration of that ion? These facts may be explained by the secondary deposition theory since the deposition in that case is due to the discharge of the  $K^+$  ion, which, being present in high concentrations, may

FIG. 8.—DIAGRAM OF LEEDS AND NORTHROP TRANSITION-POINT APPARATUS ARRANGED FOR DECOMPOSITION VOLTAGES

readily reach its decomposition voltage long before the extremely dilute silver ion. Bancroft notes that the decomposition cannot be secondary, since the  $KAg(CN)_2$  has a lower decomposition voltage than the corresponding KCN solution. This argument, however, is not valid since it is not the  $Ag^+$  ion, which is discharged,

diagram. (Figs. 7 and 8.) The curves obtained with this apparatus from tenth-normal silver nitrate, 0.275-normal potassium nitrate, and a potassium-silver cyanide solution 0.25-normal with respect to potassium and 0.1-normal with respect to silver are shown in Fig. 9. The potassium nitrate

solution was made of such strength that, assuming 75 per cent ionization for  $\text{KNO}_3$  and  $\text{KCN}$  and 100 per cent for  $\text{KAg}(\text{CN})_2$ , the concentration of potassium ion in the two solutions would be the same. The results show that the decomposition voltage of the  $\text{KAg}(\text{CN})_2$  is practically what would be expected from the concentration of potassium ion, and bears no relation to either the total concentration of silver or concentration of silver ion. This proves that the deposition of silver from complex cyanide solutions is due to the discharge of potassium ion.

There is little question then that the deposition is secondary but this explanation fails to say why we cannot accomplish the same result with a silver chloride suspension containing potassium nitrate. The reason is evidently that in so dilute a solution of silver as the chloride, the potassium liberated decomposes only water instead of silver nitrate, due to mass action, while in the case of the argenticyanide the un-ionized silver which is present in relatively large concentrations

Admitting, however, that the deposit is secondary when obtained from most complex solutions we are still uninformed as to why secondary deposition gives a smooth deposit. As previously noted, magnesium gives a very crystalline deposit so we must look elsewhere than the mere deposition by a metal of high solution-tension for an explanation of the phenomena. The presence of large crystals is due to the tendency of crystals to grow; i.e., in the case of silver the next atom of silver tends to deposit on the silver already deposited. Now in secondary deposition there is no opportunity for crystal growth since an atom of alkali metal is deposited and before it has an opportunity to grow is dissolved with the formation of silver; and since there is no other alkali metal present the next atom is deposited at random and in this way a smooth deposit is obtained. The failure to obtain a smooth deposit with magnesium is readily explained on this basis since the first bit of silver deposited forms with the still exposed magnesium a small cell in which the magnesium goes into solution on the one hand and the silver is deposited on the other.

In order to test these conclusions a solution of copper tartrate in tartaric acid was prepared by adding tartaric acid to copper acetate. The solution so obtained was about tenth-normal with respect to copper but was evidently quite low in copper ion content since the copper tartrate did not precipitate. A solution of this kind was electrolyzed using copper anode and cathode, the potential across the cell being maintained at three volts. Despite the very low concentration of copper ion the deposit obtained was very crystalline which confirms our conclusion that the presence of a metal of lower solution-tension is essential to the formation of an amorphous deposit. If now sodium sulphate was added to the copper tartrate solution and the electrolysis carried on under identical conditions, a quite smooth deposit is obtained. The addition of aluminium sulphate produces a similar result. These deposits are shown in Figs. 10, 11 and 12.

Still further results were obtained with cadmium solutions using a molar solution of cadmium chloride with the addition of  $\text{NaCl}$  and a tenth-molar solution without the addition of  $\text{NaCl}$ . These two solutions contain very nearly the same concentration of cadmium ion but the deposit from the solution containing the  $\text{NaCl}$  was markedly less crystalline. These deposits are shown in Figs. 13 and 14.

We may then define the conditions under which a complex solution will give an amorphous or nearly amorphous deposit.

(1) The presence of another metal than the one being deposited, which other metal must have a notably lower solution-tension than the one being deposited.

(2) A sufficiently complex salt that the concentration of the ion being deposited will be so low that its discharge voltage will be above that of the secondary metal.

We are indebted to Prof. V. H. Gottschalk of the Missouri School of Mines and Metallurgy for the suggestion of trying Bancroft's theory by the use of suspensions of insoluble salts.

The experiments quoted above are from the thesis of Mr. M. Y. Chang at the University of Pittsburgh.

Pittsburgh, Pa.

FIG. 9.—DIAGRAM OF DECOMPOSITION VOLTAGE-CURRENT CURVES OBTAINED WITH LEEDS AND NORTHROP TRANSITION-POINT APPARATUS

is decomposed by the potassium. In other words the secondary reaction is not an ionic one but may be represented by the equation

or possibly

It follows that the real purpose of a complex solution is to furnish a concentrated solution of the metal, but a dilute solution of its ion; further the complex salt must have so little heavy-metal ion that the discharge of the alkali-metal ion will take place first.

## Development of an Electric Furnace for Annealing Treatment and Forging of Steel\*

BY WIRT S. SCOTT

**E**XPERIMENTAL work by the Westinghouse Electric & Manufacturing Co. on register-type furnaces for forging has continued through several years. Our first investigation was with a granular graphite resistor bed 9 inches wide, 8 inches deep, by 36 inches long, for heating a furnace having an opening 36 inches wide, 24 inches deep by 10 inches high. Other resistor materials consisting of granular graphite, coke, charcoal, and finally these materials in various combinations, also in combination with carbon blocks, were given exhaustive tests, always with the same general result. It is sometimes of equal importance to know the reasons for failure as for success; hence it should be of interest to know the reasons for discarding all of the above resistor materials as being unsuitable for an electric forging furnace.

### LIMITATIONS OF CARBON RESISTORS

To secure even moderately successful results, it was found that the resistor material must be of the purest carbon or graphite. It is quite difficult to obtain a supply sufficient for operating furnaces.

If there is any slag or ashes left from the combustion of the resistor, it remains in the bed, so that the relative proportion of such material is gradually increasing with time, causing an increase in the resistance of the furnace. If the slag or ash is fusible at the temperature of the resistor bed, a clinker will be formed which very rapidly extends through the granular mass, resulting in a rapid increase in resistance and consequent failure to heat.

When the furnace was maintained for a considerable length of time at sufficiently high temperature to turn out heated steel at 1800 deg. F., we found that the temperature in the bottom of the resistor bed exceeded the safe limits of refractory materials. With a temperature of 1800 deg. F. on the surface of the bed, it was found that the temperature at the bottom was approximately 3600 deg. F. This great temperature difference is due to the electrical characteristics of carbon in that it has a large negative temperature resistance coefficient, that is to say, as the temperature increases, the resistance decreases. It is evident that the carbon in the bottom or at the center of the bed will operate at higher temperatures than the surface, which has an opportunity to radiate its heat to the surrounding air and chamber. An increase in temperature at any given part, lowers the resistance through that part, which in turn causes more current to flow, and so on, the temperature gradually increasing with the current. Conditions tend to become stable at any very high temperature, but greatly in excess of that which may be safely withstood by any refractory material now available.

In heating a piece of work in an ordinary fuel-fired furnace, heat is transferred to the work by conduction from the hot gases and by radiation from the walls. The walls are maintained at a temperature higher than

that desired at the work because they are continuously swept by the hot gases. In an electric furnace we do not have this action to heat all of the surface uniformly.

If heat is generated only on the floor of the hearth, the side-walls and roof must obtain their heat by direct radiation. If cold pieces of metal are laid closely over the surface of the resistor hearth, they will interfere with the radiation of the heat to the walls and roof directly in proportion to the amount of hearth surface they cover. This would mean that the work would be heated from the under side only, and instead of receiving heat from the walls and roof, it would be giving off heat, thereby always having a great difference in the temperature in the two opposite sides. In order to heat the upper surface to a sufficiently high temperature, the lower surface must be overheated.

### PROPERTIES OF SILICON CARBIDE

During the latter part of 1916, we began our experiments in using carbide as a resistance material. A study of the chemical and physical properties of silicon

ELECTRIC RESISTANCE ANNEALING FURNACE

carbide led us to believe that it possessed desirable qualities essential to a suitable resistor for an electric forging furnace, but also indicated that there were many difficulties to be overcome which were real problems in themselves.

The temperature of formation of this resistor is 1950 deg. C. (3542 deg. F.). The temperature of decomposition is 2220 deg. C. or 4018 deg. F. There is no oxidation of this material in pure oxygen at 1000 deg. C. (1800 deg. F.). From 1500 deg. to 1800 deg. C. (2732 deg. F. to 3272 deg. F.) oxidation is very much retarded by the fused silica coating. Neutral or reducing gases, such as carbon monoxide, nitrogen and hydrogen have little or no action.

The hardness is between the ruby and the diamond. The specific gravity is 3.12 to 3.20. Based on a specific gravity of 3.20 the weight of the solid block without pores is 199.7 lb. per cubic foot or 0.116 lb. per cu. in.

\*A paper presented before the Assn. of Iron and Steel Electrical Engineers, Pittsburgh, Apr. 20, 1918.

In order to adapt silicon carbide to its various uses the tensile strength of the bonded articles may be made to vary between wide limits. In ceramic-bonded articles where the bond does not introduce objectionable physical or chemical properties, a tensile strength of 1400 lb. per square inch may be attained. A sacrifice of resistance to heat changes and chemical actions affecting ceramic articles must be expected with high tensile strength.

The resistor is a conductor of the second class. At ordinary temperature its conductivity is very low, being several times less than carbon. With increase of temperature its conductivity increases very rapidly, as it has a large negative temperature resistance coefficient.

The resistivity of the bricks varies with differences in porosity and chemical composition. However, it is interesting to note that at temperatures above 1800 deg. F. the resistivities have approximately the same value. A general idea of the variation of the resistance will be obtained from the following:

| Deg. F. | Ohms Per Cu. Cm. |
|---------|------------------|
| 75      | 50               |
| 1000    | 18               |
| 1800    | 3.7              |
| 2550    | 0.65             |

#### EXCELLENT QUALITIES OF SILICON CARBIDE AS A RESISTOR

From a resumé of the above, it may be seen that this resistor material possesses the following excellent qualities: (1) The temperature of decomposition is above 4000 deg. F., which is approximately 1500 deg. higher than the hottest temperature required at the surface of the resistor. Due to the construction of furnace employed, the atmosphere in the furnace chamber is non-oxidizing, and under these conditions the resistor is non-consuming. (2) It may be molded in block form, allowing the heating element to be placed in any desirable position around the heating chamber. (3) Due to its high tensile strength, the roof of the heating chamber, as well as the hearth may be made out of these resistor blocks. (4) The fact that it has a large negative temperature resistance coefficient may be utilized in the control of the furnace temperature by controlling the current input to this resistor material.

#### DESIGN AND TEST OF FIRST EXPERIMENTAL FURNACES

The first complete furnace of this type which we built and which gave promise of success had an outside dimension 41 in. wide across the front, 27 in. deep and 48 in. high. It was designed with two working chambers 7 in. long by 5 in. high, for the heating of 50 lb. of steel per hour to 1800 deg. in each chamber, or a total of 100 lb. per hour for the furnace. The resistors consisted of blocks having a cross section of 4½ in. by 2½ in. passing above and below the working chamber. The resistors terminated in electrode chimneys filled with granular graphite, into which steel terminal plates extended, for external connections.

Owing to the high resistance of this type of furnace when cold, and due to the length of resistors used, a starting voltage of 220 volts was required, which was cut down in a few minutes time to 110 volts, and then gradually reduced until 60 volts was reached, which maintained the proper temperature.

The time required to bring the furnace up to an operating temperature of 1800 deg. F. was eight hours,

starting with the furnace cold. Owing to the great heat reserve capacity of the furnace, the time required in successive heatings was greatly reduced, depending upon the length of time the furnace was out of operation. In order to have the furnace available for immediate use, sufficient current was maintained on the furnace during the night to supply the radiation losses. On a 20-hour continuous forging test the average input during this test was about 18 kw. or 300 amperes at 60 volts. The charge during this test consisted of approximately four pieces of steel weighing six pounds total, each piece requiring an average of three heats, one from cold to 1800 deg. F., the other two from about 900 deg. F. to a final temperature of 1800 deg. F. The hourly output averaged 20 pounds heated from 70 deg. to 1800 deg. F. and 40 pounds from 900 deg. to 1800 deg. F.

No special attention was given to the thermal insulation of the furnace since that was of secondary importance, and a matter which could be taken care of at a later date, once we secured a suitable construction. Notwithstanding the light insulation that was used, a furnace efficiency of 41 per cent was maintained. The furnace ultimately proved unsatisfactory due to unequal heating of the two chambers.

The results of the tests proved conclusively that a temperature of 1800 deg. F. could be obtained and maintained for an indefinite period so far as the resistor material was concerned. Hand control was used entirely in the operation of this furnace, in conjunction with a circuit breaker for tripping the circuit should the current increase beyond a safe operating value.

#### DESIGN AND TEST OF SECOND EXPERIMENTAL FURNACE

The second complete furnace had an overall dimension of 46 in. wide, 38 in. deep by 48 in. high, inclusive of an iron stand 12 in. high. The radiating surface was approximately 81 sq.ft. The resistor consisted of two blocks 2½ by 4½ in. cross-section by 9 in. in length, connected in parallel, one over the heating chamber, and one underneath 2½ in. apart, forming a heating chamber 7 in. wide, 11 in. deep by 2½ in. high. The resistors were surrounded and imbedded in a refractory lining made up principally of a crucible clay and a graphite mixture. Surrounding this extremely hot area, silica bricks were used, backed up by ordinary fire bricks.

Electrode chimneys or wells were used very much the same as with the first furnace. The electrodes consisted of granular graphite and an amorphous carbon rod 4 in. square by 20 in. long embedded in each electrode well, and extending upward from near the steel terminal plate at the bottom of each well to the ends of the two resistors. The granular graphite insures electrical contact between the resistor blocks and the carbon block, and between the carbon block and the terminal plate. A cool terminal is thus obtained. The heat insulation on the outside of the furnace consisted of 4½ in. of high-grade insulating brick all around, except opposite the electrode walls and around the door. Thin sheet-steel held in place by angle-iron and tie-rods clamped the insulating bricks together.

The starting voltage on this furnace was 75 volts, and the time required to raise the temperature of the heating chamber to a forging temperature of 1800 deg. F. was two hours. The power required at full load was 10 kw. or approximately 300 amperes at 33 volts. At no load,

a consumption of 5 kw. or 200 amperes at 25 volts obtained. This corresponds to an efficiency of 50 per cent.

The longest continuous run extended over a period of 15 days, or 370 hours, the furnace being maintained continuously at a forging temperature of 1800 deg. F. After these tests, an examination of the resistors was made, but no perceptible effect due to heating could be determined.

The control equipment consisted of a 110-volt transformer with knife switches for obtaining starting voltage, and interlocked magnet switches, push-button-operated, for obtaining the required running voltage. A circuit breaker was used as in the first case for protecting the furnace against an increase in current above the operating value.

The first furnace to be placed in continuous operation under actual shop conditions was made early in 1917. This furnace, a duplicate of the one last described, was installed in the tool-forging shop of the Westinghouse Electric & Manufacturing Company, and while it was considered that the furnace was still in its experimental stages, it was essential that we gain the experience of knowing how it would stand up under regular shop conditions.

Several failures of the furnace were recorded, but in each case the failure was due to the improper functioning of the control equipment which we were developing and experimenting with at that time. This furnace has been in operation for a period of one year, with highly encouraging results. Many runs have been made of continuous operation for periods of 400 and 500 hours, forging high-speed steel to 1850 deg. F. and drop-forging at 2200 deg. F. without any records of resistor failure, or any perceptible deterioration in the resistor due to the high operating temperature. One run of 500 hours was made at a temperature of 2650 deg. F. without experiencing any difficulty whatever.

For high-speed steel work, as it was found advisable to preheat the steel before placing it in the heating chamber, a preheating chamber was constructed under the heating chamber, consisting of an opening in the front of the furnace just below the lower resistor, into which the tools could be placed for preheating to eliminate strains that otherwise would be set up in the steel when placed in the furnace.

Another furnace has been built and placed in operation at our works, having a heating chamber 18 inches wide, 12 inches deep and 4½ inches high. The capacity

of this furnace is 20 kw., the starting voltage 220, and the running voltage 70. The efficiency is 60 per cent. This furnace is designed to operate on steel drop-forging requiring a temperature of 2300 deg. F.

#### DEVELOPMENT OF AUTOMATIC CONTROL EQUIPMENT

The control equipment at the present time is not completely automatic. That is to say, the furnace is not automatically brought up to the required temperature, but once the required temperature is obtained, then the control equipment will maintain that temperature within certain limits. Interlocked knife switches are used for connecting to the starting taps on the transformer.

As the furnace increases in temperature it is necessary to step down to lower voltages. The lower voltage taps are controlled by means of magnet switches operating over a relatively small percentage of the voltage range in order to obtain close temperature regulation.

The control equipment thus far developed is semi-automatic in its action, and may be used with entire satisfaction where the operator has a proper appreciation of the functioning of the control equipments. However, it is our intention ultimately to develop a complete automatic control equipment, which we hope to have perfected at an early date.

The general type of the furnace such as we have developed has a very wide application, but our ex-

periments thus far have been largely confined to forging, vitreous enameling, and for the reheating of glassware. A special furnace has been constructed and is successfully operated for the forming of lamp chimneys.

#### DISADVANTAGES OF FUEL-FIRED FURNACES FOR FORGING

Forging requires an operating temperature of from 1800 deg. to 2300 deg. F., depending upon the kind of steel used. One great difficulty with a fuel-fired furnace is not in the ability to obtain a sufficiently high heat, but in uneven heating. It is almost impossible to obtain uniform temperature throughout the entire chambers; consequently when the furnace is operated on a production basis, with several pieces being heated at one time, some of the pieces of work will be much hotter than others. The pieces in the hottest portion in all probability will heat much too rapidly, with the result that either the corners of the tools are burned before the material is heated clear through, or if it is removed before the surface burns, the center has not reached a suffi-

ELECTRIC RESISTANCE ANNEALING FURNACE

ciently high temperature. In this case the soft outside will yield much more readily than the hard inside, with the result that the outer particles will be torn asunder while the inside will be sound. The loss through oxidation takes place while the work is being heated in a fuel-fired furnace and also after it has been withdrawn and is being forged. The oxidation in the furnace is by far the larger of the two.

Annealing or softening is accomplished by heating steel to a red heat ranging from 1300 deg. to 1600 deg. F., depending upon the grade of steel, and then cooling it slowly. If the temperature is carried too high, it may leave the steel actually harder than the proper heat would leave it, besides running the risk of forming a scale. If scale is raised on a piece of steel, this scale will be a granular oxide of iron, and may spoil the tools used to cut it, sometimes changing the structure of the steel, making it brittle and causing it to crack in hardening. The effect of heat on steel may be noted by taking a bar of steel nicked in 10 or 12 places about  $\frac{1}{8}$  inch apart, heating it in a fuel-fired furnace until the end is up to a good white heat, and then plunging it into cold water. In breaking off the pieces at each nick, it will be seen that characteristic changes have taken place in the steel. The end of the rod which had been over-heated will be very open or crystalline in structure, the succeeding pieces becoming closer and closer in grain until one piece is formed possessing a close, even grain, the structure desired.

For every variation in the temperature there is a variation in grain of the steel. The effect of too high a heat is to open the grain, to make the steel coarse. The effect of irregular heat is to cause irregular grain, irregular strains and cracks in the steel.

#### ADVANTAGES OF ELECTRIC FORGING FURNACE

The furnace described offers an ideal solution for the conditions as above outlined, because:

(a) Uniform temperature is obtained in all parts of the heating chambers.

(b) The temperature found to produce the most satisfactory results may be obtained and maintained indefinitely.

(c) A neutral atmosphere is obtained in the furnace chamber, thereby eliminating the major part of the oxidation of the steel.

For a given class of work subjected to a given heating operation the following conditions must apply.

1. The rate at which the work is heated is capable of infinite variation, but there must be some best sequence of heating.

2. The temperature difference between the heating medium and the work may be almost any value, but there must be some best value.

3. The maximum temperature to which the work is heated may be within fairly wide limits, but there must be some most satisfactory temperature to which each grade of steel should be heated.

An electric furnace permits of doing such experimental work as will exactly determine these factors; and, once they have been determined, it permits an operator to duplicate these results in operation: the ultimate feature in which we are interested.

Pittsburgh, Pa.

## Société Coopérative for Belgium

In view of the critical situation which will result for Belgium through the disasters caused by the depredations of the enemy, his removing of tools, raw materials, manufactured products, etc., there has been created, with the coöperation of and under the control of the Belgian State, an organization having for its object the economical reconstruction of Belgium, entitled "Comptoir National Pour La Reprise de l'Activité Economique en Belgique (Société Coopérative).

This organization, in helping industry and trade, by enabling them to purchase the tools and all necessary raw materials, will not only reconstruct the economic situation of Belgium, but will put an end to the sufferings of the working classes by enabling them to start working in the reconstructed shops. All materials required for reconstruction are of interest to this organization, including materials for construction of buildings, leathers, textiles, farming implements, chemical products, wood machines, electrical materials, optical instruments, motor cars, vans, wagons, oils and greases of all kinds, refractory materials, etc. American manufacturers who have such materials to offer for export, either now or after the war, are requested to send catalogs and tariffs in triplicate.

## Wood Alcohol for Motor Purposes

According to Consul General Albert Halstead, Stockholm, the war has naturally tended to cause neutral nations that are unable to procure their usual supplies of manufactured and other products to start to manufacture for the home market, and often to make substitutes. As a result these markets for American manufactures are certain to be found more competitive in many lines after the war, while in others to be unprofitable because of the success of domestic industry. However, a business man expressed the opinion the other day that perhaps 60 per cent of the newly established industries in Sweden would be unable to withstand foreign competition when it is resumed. From Germany systematic dumping was looked for, plans for which have already been made.

The impossibility of securing gasoline had almost driven automobiles from the streets of Stockholm. Recently, however, some taxicabs have reappeared which use wood alcohol instead of gasoline.

The newspapers of February 15 announced the formation of the Sulphite Mills Sales Co., with a capital of from \$53,600 to \$160,800 and representing 13 mills. Two are already using their waste lye for the manufacture of spirits, a number are soon to begin such operations, and others are planned. The production of the completed mills is said to amount to 15,000,000 liters (3,962,660 gallons) of 100 per cent pure alcohol a year. When all the mills are operated, their total capacity is calculated at 25,000,000 liters (6,604,440 gallons), and if all the Swedish sulphite mills were to produce spirits, the aggregate capacity would, it is said, reach 40,000,000 liters (10,567,100 gallons) annually. Continued Government assistance is expected for this industry.

# Destructive Distillation of Oil Shales

Description of Products, Influence of Sulphur, Oxygen and Nitrogen Content—Commercial Possibilities

By JAC C. MORRELL AND GUSTAV EGLOFF

THE oil shale used in the present experiment was derived from the Green River formation, which belongs to the Eocene period consisting mainly of shale. The outcrop which consists of a greyish-white color, but really shows bands of white to grey, was not selected for retorting samples, but those which showed a brownish to black appearance on the freshly broken surfaces. This shale was tough and showed no bedding planes, but they were developed by retorting. Plant structure was clearly noted in a number of the pieces which indicated its derivation, and when freshly broken gave the faintest odor of petroleum at times.

## EXPERIMENTAL METHOD

The first apparatus used for distilling the shale was a modification of that used by the United States Geological Survey. The permanent gases formed after being led through an ammonia scrubber were passed successively through a gas meter, a scrubber with 1.84 specific gravity sulphuric acid to remove unsaturated gases and another meter to record unabsorbed gases. The shale was broken up into pieces about three-fourths of an inch square, and a one-pound charge was introduced into the retort. The retort was slowly heated with a five Bunsen burner cluster until a dull-red heat was attained, and kept at this temperature for about four hours. The apparatus was then disconnected, the condensed liquids consisting of oil and water placed in a graduate and allowed to stand until a sharp line marked off the oil from the water and the quantity of each was then read off. The liquids were then placed in a separatory funnel, and allowed to stand for about twelve hours, a clean separation then being made. The water portion was added to the liquor (dilute sulphuric acid) from the ammonia scrubber and the ammonia determined by the Kjeldahl method. The oil was later subjected to a distillation analysis, and the various fractions further examined.

Further tests were made to determine solubility, ash, fixed carbon, and volatile matter.

The products resulting from the retorting of one pound of oil shale was not sufficient to make more than the following data in tables No. I and No. II:

TABLE I.

|                                 | Per Cent |
|---------------------------------|----------|
| Spent shale                     | 84.1     |
| Ash                             | 61.3     |
| Fixed carbon                    | 22.8     |
| Total volatile matter           | 38.7     |
| Oil                             | 7.49     |
| Water                           | 2.79     |
| Soluble in CS <sub>2</sub>      | 0.13     |
| Ammonia as sulphate of ammonium | 1.27     |

TABLE II.

Products Produced per Ton

|                     |              |
|---------------------|--------------|
| Oil                 | 20.3 gal.    |
| Total permanent gas | 1.947 cu.ft. |
| Sulphate of ammonia | 25.4 pounds  |

Since the retorting of one pound of oil shale did not give sufficient oil for close analytical results, a

larger charge was taken consisting of twelve pounds. For this purpose a horizontal retort was used of 8" diameter and length of 18" and made of double extra heavy lap welded steel tubing, which was built so as to conduct experiments later of retorting oil shale under vacuum and pressure, thereby varying the type product formed.

The method of retorting was by means of direct heating, with a thermometer inserted into a well in the body of the shale, and another thermometer in the vapor line of the retort. In table No. III, the still and the vapor-line temperature are shown. The last hour of retorting showed no liquid or vapors coming over, hence it was concluded that the oil had all been distilled out of the shale.

| 3:55 p.m.  | (a)                          | 355                               | Very strong odor of ammonia         |
| 4:25 p.m.  | (a)                          | 360                               |                                     |
| 5:55 p.m.  | (a)                          | 370                               |                                     |

Total retorting time 6 hours.

(a) Above 400°C. Still, reddish, white heat.

During the retorting of the shale, distillates of oil and water were collected every 100 cc. and the endeavor was made to distill at the rate of 100 cc. per hour. The gravity of the oil portion was taken, and the curious phenomenon was noted that the gravity of the oil in the first fraction was higher than the second and third and then the gravity increased again. The data indicates two maxima and a minimum in the values of the gravity of the various cuts. This is unusual, for the specific gravity of an oil upon distillation increases with increase of the boiling point. This phenomenon requires further investigation as it is certain that we have to deal with a different group of compounds from what is ordinarily known. This may be due to heterocyclic nitrogen compounds. Furthermore, during the retorting of the shale, droplets of liquid falling from the end of the condenser at times were insoluble in the oil layer and passed through the water layer to the bottom of the receiver. This was clear proof that we had to deal with oily material having specific gravity greater than water. There was only a trace of this material in comparison to the whole and not sufficient to test for; hence, to investigate this point a ton or more of shale would have to be retorted.

It was further noted that as the retorting proceeded the ammonia content of the water layer of the distilla-

tion cuts increased, which indicated that the yield of ammonia increases with temperature to a maximum, and then more than likely decreases.

The data is expressed in table No. IV.

TABLE IV. PRODUCTS OVER FROM RETORTING

| Sample     | Total e.e. Over Oil and Water | e.e. Oil Over | e.e. Water Over | Specific Gravity of Oil 15.5°C. | Beaumé Gravity of Oil 60°F. |

## DISTILLATION ANALYSIS OF RECOVERED OIL

The color of the recovered oil was a dark brownish red. Upon distillation, the analytical data is given in table No. V, the first 10 per cent of which showed a strong lemon color increasing in intensity until 40 per cent came over. The color of the distillates became darker, merging into wine red, with a black solid residuum in the flask, which showed a tendency toward cracking at a temperature of 360° C. The phenomenon of a liquid coming over during retorting which was partially insoluble in the shale oil and heavier than water has already been referred to. The same type reddish liquid came over in traces upon distilling the recovered oil which was insoluble in the lemon-colored distillate and fell to the bottom of the receiver. What type compound or compounds this represented, as to whether it was a nitrogen or sulphur compound with a low boiling point and high specific gravity, has not been ascertained as yet.

Table No. VI is the distillation data of the crude benzine cut of the recovered oil which was taken as the first 50 per cent over at a temperature of 435° F. and averaged Beaumé Gravity of 42.9.

In analyzing the data to arrive at a commercial motor fuel having an end point distillation of a present value of 410° F. and 57-58° Beaumé, we find that 85 per cent gives an end point of 405° F. but a Beaumé gravity of 45.9°. Although the volatility of the mixture will pass for a motor fuel, the gravity is very low; furthermore, the 85 per cent contains 36 per cent of substances combining with 1.84 sulphuric acid. Upon neutralizing the excess sulphuric acid with 6° Beaumé caustic soda and washing with water and drying over calcium chloride, a deep reddish black oil remained which would be the so-called motor fuel. For upon redistillation of the refined reddish black "gasoline cut", seventy per cent of distillate was a deep lemon color which upon standing developed a deep reddish-brown color with a Beaumé gravity of 47.3 which corresponds to a heavy naptha in petroleum technology. Much technical work will have to be carried on to refine the crude benzine from oil shale retorting so as to make a marketable motor fuel for internal combustion engines as at present constructed. To work up this oil into a marketable motor fuel is a much more difficult problem than the simple one now presented to the petroleum industry, due to the fact that this oil undoubtedly contains sul-

phur, nitrogen, highly unsaturated hydrocarbons of the terpene type, aromatic and phenolic compounds.

The higher boiling point cuts show beautiful lubricating oils of similar properties to those obtained from California and Russian oils. The oils must be highly naphthenic in character, and this point will be reported upon more fully in a later paper.

TABLE V. DISTILLATION ANALYSIS OF RECOVERED OIL

|                      |                   |              |

## UNSATURATED HYDROCARBONS

In the cracking of hydrocarbon material in general the four types predominant are:

1. Paraffins.
2. Unsaturated compounds as acetylenes, olefins, and terpenes.
3. Naphthenes.
4. Aromatics.

Since it is generally held that the heat treatment of oil shale is a cracking phenomena, then the type of compounds formed under thermal treatment is a function of the temperature under which retorting takes place. Since this is so then the percentage of unsaturated hydrocarbons in the distillates must be dependent upon the percentage of carbon and hydrogen in the oil shale under treatment at the particular stage of shale decomposition. But, the problem is greatly complexed by the presence of sulphur, nitrogen and oxygen present in the starting material as is witnessed by the

decreasing yield of water every 100 c.c. distillate over, and the increase of the ammonia yield with increase of temperature.

In table No. VII, the surprising result is shown of the percentage of unsaturates indicating two maxima, and one minimum value. A maximum of 32 per cent is shown in the first ten per cent cut decreasing to twenty-four per cent and then reaching a maximum value in the last cut. In all thermal and pressure treatment of hydrocarbon material as petroleum oils the percentage yields of unsaturates increase from a minimum to a maximum and then a minimum value. There is a question as to whether the absorbed by 1.84 specific gravity acid method<sup>1</sup> registers only unsaturated hydrocarbons. From the amount of nitrogen and sulphur compound and water distilled over, we may well be dealing with some alkylamines, diamines, imines, amides, thioamides, anilides and nitriles, pyridine, pyrrol and quinoline bases.

TABLE VII. PER CENT OF UNSATURATES IN DISTILLATION CUTS FROM RECOVERED OIL

| Per Cent Unsaturates in Recovered Oil, 31.0 |  | Per Cent Unsaturate in Cuts |  |
|---------------------------------------------|--|-----------------------------|--|
| Distillation Cuts Per Cent                  |  |                             |  |
| 0-10                                        |  | 32                          |  |
| 10-20                                       |  | 26                          |  |
| 20-30                                       |  | 24                          |  |
| 30-40                                       |  | 26                          |  |
| 40-50                                       |  | 30                          |  |
| 50-60                                       |  | 36                          |  |
| 60-70                                       |  | 40                          |  |
| 70-80                                       |  | 50                          |  |
| 80-90                                       |  | 50                          |  |
|                                             |  | Whole mass solid            |  |

A. H. Allen<sup>2</sup> gave a series of values upon the reactive properties of olefins in shale and petroleum products. He assumed that the relative proportion of olefins present in two products of similar density and boiling points is fairly accurately indicated by the power of assimilating bromine. Hence, the following table No. VIII, would show the relative amounts of olefins present in shale and petroleum products:

TABLE VIII.

|                 | Shale Products           |                             | Petroleum Products       |                             |
|-----------------|--------------------------|-----------------------------|--------------------------|-----------------------------|
|                 | Specific Gravity 15.5°C. | Per Cent Bromine in Product | Specific Gravity 15.5°C. | Per Cent Bromine in Product |
| Gasoline        | 0.665                    | 41.6                        | 0.652                    | 4.8                         |
| Naphtha         | 0.718                    | 48.7                        | 0.690                    | 4.8                         |
| Burning oil     | 0.801                    | 27.9                        | 0.800                    | 14.7                        |
| Burning oil     | 0.806                    | 26.7                        |                          |                             |
| Lubricating oil | 0.875                    | 31.2                        | 0.862                    | 17.7                        |
| Lubricating oil | 0.889                    | 36.0                        | 0.905                    | 24.1                        |

Although Allen does not give details as to the method of production, conditions under which olefins formed, and sources of his shale and petroleum products, the data are interesting in qualitatively verifying the data in table No. VII. The shale oil products, as the specific gravity increases, shows a decrease in unsaturates and then an increase similar in nature to those found by the writers. However, it is certain that petroleum products are not complexed to the same extent by various nitrogen, oxygen and sulphur compounds as are the oil shale products.

#### AROMATIC HYDROCARBONS

The formation of aromatic hydrocarbons during the decomposition of the bituminous material present in the shale was suspected, hence a test was made for benzene, toluene, xylenes, naphthalene and anthracene. The oil was fractionated by means of a Hempel

Column several times, and the cut between 78° and 82° C. analyzed for benzene by using a 2:1 concentrated sulphuric-fuming nitric acid mixture, and heating so as to form dinitrobenzenes. The dinitrobenzenes were treated with alcohol and 1-3 dinitrobenzene crystallized out with a melting point of 89.7° C. Toluene was tested for in the distillation cut from 107°-113° C., by treating with a concentrated nitric sulphuric acid mixture according to the Langenscheidt method.<sup>3</sup> The TNT formed was recrystallized from alcohol and gave a melting point of 80.2° C. The xylene cut of 137-142° C. was nitrated in a similar manner, but care was taken so as not to form benzoic or phthalic acid from the oxidation of the side chains. The 2-4-6 trinitro-xylene was isolated by crystallization and identified by its melting point of 181.5° C.

The tests for naphthalene and anthracene were subject to great difficulties due to the large amount of solid paraffin present and their separation was not successful. However, it is unlikely that more than a trace of these two hydrocarbons could have been present due to the relatively low temperature of retorting the shale. The formation of naphthalene and anthracene are relatively high temperature reaction products.<sup>4</sup> But, it is certain that naphthalene and anthracene would form at higher temperatures in the destructive distillation of oil shale.

The percentage of aromatic hydrocarbon formation of benzene, toluene and xylene under the conditions of these experiments was small, but, the recovered oil could be retorted again in gas machines and give commercial yields of these products.

#### ANALYSIS OF WATER RESULTING FROM THE THERMAL DECOMPOSITION OF THE OIL SHALE

The water distillate was an amber-colored liquid with a strong odor of ammonia and heterocyclic nitrogen compounds like pyrrol, pyridine and similar substances. The percentage of this water distillate upon the total liquid recovered was 25.2 and upon a weight basis of a ton of shale, 3.0 per cent. The oil and water distillate as the retorting progressed, was collected in 100-c.c. samples. The following table No. IX, gives the per cent of water in the 100 c.c. fractions of oil and water distillates.

TABLE IX.

| 100 c.c. Samples   | Per Cent of Water |
|--------------------|-------------------|
| 1                  | 59.0              |
| 2                  | 37.0              |
| 3                  | 26.5              |
| 4                  | 13.0              |
| 5                  | 11.0              |
| 6                  | 17.0              |
| 7 (Basis 100 c.c.) | 9.2               |

Upon analysis a composite sample of the water distillate gave the following data in table No. X.

TABLE X.

|                                     |                     |
|-------------------------------------|---------------------|
| Specific gravity                    | 1.022               |
| H <sub>2</sub> S per cent           | 0.179               |
| CO <sub>2</sub> per cent            | Trace               |
| NH <sub>3</sub> per cent            | 1.580               |
| Ether extraction per cent           | nil (practically)   |
| CS <sub>2</sub> extraction per cent | 0.0225              |
| Reaction to litmus                  | alkaline (strongly) |

In the extraction by carbon bisulphide a wax-like solid was separated which had a pungent odor of heterocyclic nitrogen compounds, stronger than the original water solution. No further work was possible

on this waxy solid due to the small amount obtained. To investigate this point would require the retorting of at least one ton of oil shale.

### PHENOLS

The formation of phenolic compounds due to retorting oil shale is to be expected, when one considers the amount of oxygen in the starting material, and the percentage of water and oil distillate given off. But, the yield seems to be much smaller than one would be led to expect. Thomas Gray<sup>5</sup> in 1902 treated 3,200 gallons of "green naphtha" obtained from Scotch shale with 28 gallons of (27 per cent) sodium hydroxide solution. The aqueous solution was separated and the phenolic compounds precipitated out of solution with an excess of sulphuric acid which yielded approximately one and one-half gallons of crude phenols called "creosote oil" or 0.047 per cent of the "green naphtha" started with. During the distillation of a portion of this brown oily liquid the odor of sulphur dioxide, and hydrogen sulphide was noted.

Four hundred grams of "creosote oil" upon distillation gave the following results in table No. XI.

TABLE XI. CREOSOTE OIL

| Temperature  | Sixth | Distillation |
|--------------|-------|--------------|
|              | Grams | Per Cent     |
| Below 195°C. | 47.8  | 11.95        |
| 195 to 200   | 42.4  | 10.60        |
| 200 to 205   | 49.4  | 12.35        |
| 205 to 210   | 46.2  | 11.55        |
| 210 to 215   | 36.4  | 9.13         |
| 215 to 220   | 22.7  | 5.68         |
| 220 to 230   | 21.6  | 5.40         |
| 230 to 255   | 3.7   | 0.93         |

The first distillation residue above 230° C. was pitch-like in character and was 16 per cent of the creosote. After thirteen distillations phenol was found to be present in a small amount. The (o) and (m) cresols were separated but no (p). The 1, 2, 4 and 1, 3, 5 xylenols were identified and a very small quantity of guaiacol. In table No. XII is given the approximate percentages of the phenols, as calculated from the data of Gray.

TABLE XII.

Phenols from 3,200 gallons "Green Naphtha"  
1.5 Gallons Creosote Oil from 3,200 Gallons "Green Naphtha"

The percentage of phenolic compounds has been calculated on the basis of the 3,200 gallons of "green naphtha" started with, by taking the mean of the values recorded by Gray. These percentage yields indicate the slight phenolic compound formation due to the thermal decomposition of oil shale, when one considers that several hundred tons of oil shale are required to form 3,200 gallons of "green naphtha." Despite this large amount of oil shale retorted, Gray stated that to separate the phenolic compounds formed, even a larger quantity of "green naphtha" would be necessary; hence, probably, 1,000 or more tons of oil shale retorted would be necessary to determine the various phenols present. It has been stated that American oil shale will produce greater quantities of phenolic

compounds than the Scottish. This may be so, but as far as the writers are aware no experimental data has appeared.

In the present work a careful analysis was made of the recovered oil for phenolic compounds, but the sample obtained from the retorting of shale was much too small for anything more than a mere qualitative test. As the above work by Gray indicates, a very large amount of oil would have to be treated to isolate the phenolic compounds present.

A 50-c.c. sample of the cut between 170°-190° C. of the recovered shale oil was treated, with a 20 per cent sodium hydroxide solution, and then neutralized with sulphuric acid. The solution was filtered and distilled, a strong odor of phenol being noted at the end of the condenser. Part of the distillate was treated with bromine water, and a very small slightly yellowish precipitate of 2, 4, 6 tribromophenol was indicated. The distillate was also treated with ferric chloride which gave a violet coloration in the solution which is a characteristic test for phenol, but it must be remembered that other phenolic compounds give violet colored solutions upon treatment with ferric chloride. The phenol present was no more than a trace. A further search was made to isolate other phenolic compounds of the di-tri and tetra hydroxy benzene and hydroxytoluene, xylene and mesitylene, but without success with the amount of oil at hand. A piece of research of the highest importance in connection with American oil shale retorting is to determine the commercial yields of not alone the phenolic compounds of the above type but also as to whether thymol and carvacrol are formed and furthermore, phenol—alcohol—ethers must also be produced of the type of anisole, phenetole and phenol ether, as diphenyl oxide.

### THIO-DERIVATIVES OF PHENOL

Due to the fact, that the water distillate resulting from the thermal treatment of the oil shale under discussion gave 0.179 per cent of hydrogen sulphide, the writers endeavored to isolate and identify thiofen, mercaptans of the paraffin and aromatic types. That thiophenol, phenyl sulphide, thioanisole, thiophenetole and similar compounds are formed is reasonably certain, for their formation is along similar lines to the oxygen alcohols, ethers of the paraffin and aromatic series. In this communication the only sulphur compound isolated and identified with certainty was hydrogen sulphide, and further work along this line awaits the retorting of a very large quantity of shale, as also for the further identification of phenolic compounds in shale oil.

### HETEROCYCLIC NITROGEN COMPOUNDS

The researches of Anderson,<sup>7</sup> Hofman<sup>8</sup> and Stenhouse<sup>9</sup> have indicated that when nitrogenous material of organic derivation is subjected to destructive distillation some of the products formed are ammonia and volatile organic bases. It would then be expected that bituminous material like oil shale containing nitrogen would likewise produce heterocyclic nitrogen compounds of the pyrrol, pyridine, quinolind and acridine series, similar

<sup>7</sup>Edinburgh Phil. Trans. XX 2, 247. Jour. Chem. Soc. 4, 112, 1852.

<sup>8</sup>Jour. Chem. Soc. 4, 304, 1852. Ibid 3, 279, 1851.

<sup>9</sup>Jour. Chem. Soc. 3, 399, 1851.

<sup>5</sup>Soc. Chem. Ind. Jour. 21, 845, 1902.

to the destructive distillation of wood, bone, coal and the varied nitrogen containing organic material.

Williams, working upon a crude naphtha resulting from the retorting of a Dorsetshire shale rich in fossilized animal remains isolated a number of heterocyclic nitrogen compounds of the pyrrol and pyridine series. He treated crude naphtha with sulphuric acid to extract the bases. The tarry matter was separated by boiling with water, during which pyrrol was evolved, and tested for by means of fir wood moistened with hydrogen iodide which turned to an intense purplish red. The sulphuric acid was then neutralized with potassium hydroxide and subjected to distillation. A nonbasic oil was separated by saturating the distillation product with hydrogen iodide, and the liquid again neutralized, and distilled. The ammonia was collected by passing through a strong solution of potassium hydroxide in which the bases were insoluble. The water present was taken up and removed by sticks of sodium hydroxide. The liquid was refractionated many, many times and fractions collected every 10° F.

The bases obtained were limpid, colorless and highly refractive. A persistent odor was noted which was pungent. The fractions burned with a smoky flame and fumed strongly in the presence of hydrogen iodide. The bases dissolved in hydrogen iodide with an evolution of heat and formed deliquescent salts. They dissolved readily in alcohol or ether. Upon the addition of cupric nitrate a complex precipitate like  $(\text{CuNH}_3)_2$  was formed which dissolved in excess. The bases with boiling points below 320° F. dissolve readily in water, but above this temperature to a lesser extent. Those with boiling points below 320—10° F. gave a beautiful green coloration upon treatment with bleaching powder.

The volatile bases were analyzed by means of precipitation with  $\text{PtI}_4$  (author states  $\text{PtI}_2$ ) and crystallization of platinum salts of these bases which is a much more reliable method than distillation. The following heterocyclic nitrogen compounds were isolated and identified from a crude naphtha resulting from the retorting of oil shale.

|                              |                                                 |
|------------------------------|-------------------------------------------------|
| Pyrrol                       | $\text{C}_4\text{H}_7\text{N}$                  |
| Pyridine                     | $\text{C}_5\text{H}_7\text{N}$ (Formula?)       |
| Picoline (methyl pyridine)   | $\text{C}_6\text{H}_7\text{N}$ (Formula?)       |
| Lutidine (dimethyl pyridine) | $\text{C}_7\text{H}_9\text{N}$ (Formula?)       |
| New base (?)                 | $\text{C}_8\text{H}_{11}\text{N}$ (Formula?)    |
| Parvaline                    | $\text{C}_{10}\text{H}_{13}\text{N}$ (Formula?) |

Beilby<sup>11</sup> believes that animal vegetable matter tends toward the formation of carbonaceous material with the original nitrogen being retained. He states that all oils reacting from the destructive distillation of carbonaceous material containing nitrogen, more or less altered older organic remains, behave much the same as the original substance would have done. Albumen and gelatin and corresponding vegetable matter yield on thermal distillation:

1. Ammonia.
2. Oil rich in alkaloidal bodies.
3. Carbonaceous residue containing large proportions of original nitrogen.

When more or less altered deposits of peat, coal, shale, etc., are distilled a similar redistribution of the

nitrogen takes place. A distribution of the nitrogen in shale is shown after distillation in table No. 13.

TABLE XIII

|                              | Per Cent Nitrogen |
|------------------------------|-------------------|
| Ammonia in water distillate. | 17 0              |
| Oil as alkaloidal tars       | 20 4              |
| Coke residue                 | 62 6              |

He argues that the nitrogen of the shale started with upon retorting redistributes itself with a higher percentage in the higher boiling point fractions and reaches a maximum in the residue. The alkaloidal tars studied by him were approximately one-fourth by weight of the oil distillate. In the particular distillate studied the oil portion contained 1.16 per cent nitrogen while the alkaloidal tar contained 4 per cent. Upon redistillation of the tar and making ten fractions, the distribution of the nitrogen was, as is shown in table No. 14, although some of volatile alkaloids were lost.

TABLE XIV.

| Fraction | Per Cent Nitrogen |
|----------|-------------------|
| 1        | Lost              |
| 2        | 3 54              |
| 3        | 3 37              |
| 4        | 3 35              |
| 5        | 3 34              |
| 6        | 3 47              |
| 7        | 3 54              |
| 8        | 3 35              |
| 9        | 3 54              |
| Residue  | 4 00              |

The latter fractions were subjected to a red heat which indicates the relative stability of the nitrogen compounds. The formation of ammonia from reforming shale is a function of the conditions of temperature, time, retort and other factors, and that when heating is conducted slowly a decomposition of the alkaloids takes place producing more ammonia. The shale referred to above was then distilled very slowly and gave the following results in table No. 15.

TABLE XV.

|                                               | Per Cent Nitrogen |
|-----------------------------------------------|-------------------|
| Total nitrogen                                | 0 70              |
| As ammonia in water distillate                | 0 23              |
| As alkaloids in oil                           | 0 14              |
| In coke                                       | 0 32              |
| Loss                                          | 0 01              |
| Calculating on Basis of Total Nitrogen as 100 |                   |
| As ammonia in water distillate                | 32 8              |
| Alkaloids in oil                              | 20 0              |
| In coke                                       | 45 7              |
| Loss                                          | 1 5               |

The latter experiment shows clearly the time factor in the increasing of the yield of ammonia at the expense of the alkaloids present in the residue coke.

Beilby made a series of nitrogen determinations of various oils, ozokerite, residuums and coke from Scotch shale, American residuum and coke and Galician ozokerite, the results of which are shown in table No. 16.

TABLE XVI.

|                               | Per Cent of Nitrogen |
|-------------------------------|----------------------|
| Scotch shale oil from retorts | 1 160                |
| Scotch petroleum or ozokerite | 2 296                |
| American petroleum residuum   | 0 080                |
| Galician ozokerite            | 0 188                |
| Scotch basic tar              | 3 900                |
| American residuum tar         | 0 710                |
| Scotch crude still coke       | 3 200                |
| American crude still coke     | 0 375                |

The work of Beilby indicates that the nitrogen present in the original bituminous material increases in the latter fractions during retorting, reaching a maximum in the residue; furthermore, that during distillation of the shale only the more volatile alkaloids come off and the residue still contains the less volatile or pitchy nitrogenous bodies, and that it is probable that there are series of unbroken continuity from the volatile

<sup>11</sup>Chem. Soc. Jour. 7, 97, 1854. Philo. Mag. 11th ser. vol. 8, 203, 1854.

<sup>12</sup>Soc. Chem. Ind. Jour. 3, 216, 1884

pyridine, picoline up to pitchy or coke-like substances. Diagrammatically this is shown as follows:

| Oil Shale                                                |                                  |                                                           |
|----------------------------------------------------------|----------------------------------|-----------------------------------------------------------|
| Hydrocarbons                                             | Alkaloids (?)                    | Higher alkaloids or substances like Carbazole $C_8H_7-NH$ |
| $C_2H_4$ to $C_{20}H_{40}$<br>$C_3H_8$ to $C_{20}H_{42}$ | $C_8H_9N$ to $C_{12}H_{17}N$ (?) |                                                           |

In the present work the heterocyclic nitrogen compounds were not isolated due to the amount of distillate oil and water recovered not being sufficient for a close analysis. Attempts were made to isolate the volatile bases by means of precipitation and crystallization of the hydrochlorides, sulphates and platinichlorides, but too many complexes were formed which we were unable to separate—due to not being able to fractionate the starting material into close boiling fractions. However, that pyridine and its homologs are present is certain, for their characteristically pungent odor was noted clearly. The further study of these heterocyclic nitrogen compounds will be carried on, when sufficient starting material is obtainable. Due to the close analogy of the thermal decomposition products of bituminous material containing nitrogen, oxygen and sulphur, as coal, bone, wood and shale, similar volatile base type products have been isolated. It is suggested that when shale oil is thoroughly investigated, compounds of the furfurane, thiophene, pentamethylæne oxide and penthophene series will be isolated. They are so closely interwoven, synthesized and analogous in their behavior to some extent to the benzenes, phenols and one another as the formation of dimethyl furfurane, thiophene and pyrrol from acetyl acetone, shows that similar synthesizing must occur when oil shale is subjected to thermal treatment.

#### PRODUCTS RECOVERED ON BASIS TON OIL SHALE RETORTED

In table No. 17, the results from retorting twelve pounds of oil shale are tabulated, with percentage yields of various products. Furthermore, the products based upon a ton of oil shale compare fairly closely with the results obtained by retorting one pound of the same shale. This particular oil shale from Colorado would average between twenty and twenty-one gallons of oil per ton and approximately twenty-five pounds of ammonium sulphate.

TABLE XVII. PER CENT PRODUCTS FROM OIL SHALE

| Oil Shale                           | Pounds | Kilograms     | Per Cent |
|-------------------------------------|--------|---------------|----------|
| Charge used                         | 12.00  | 5.87          |          |
| Spent shale                         | 10.00  | 4.89          | 83.3     |
| Oil recovered                       | 0.91   | 0.45          | 7.6      |
| Water recovered                     | 0.35   | 0.17          | 3.0      |
| Ammonia                             | 0.04   | 0.21          | 0.3      |
| Gas and loss                        | 0.61   | 0.34          | 5.8      |
| Products per Ton Oil Shale Retorted |        |               |          |
| Oil                                 |        | 20.7 gal.     |          |
| Total permanent gas                 |        | 1,920 cu. ft. |          |
| Sulphate of ammonia                 |        | 23.3 lb.      |          |

The following list of compounds have been isolated by various workers in oil shale retorting. They are fairly well diversified, but with further research in all likelihood there will be approximately as many different compounds identified as there have been from coal tar. Shale oil is an exceedingly complex mixture of hydrocarbon, oxygen, sulphur and nitrogen compounds

of complex structure, which would require the highest technical skill to separate for industrial use.

#### COMPOUNDS ISOLATED FROM OIL SHALE RETORTING

|                  |     |            |     |

#### GENERAL SUMMARY

1. The derivation of oil shale is in all probability of the same origin as petroleum oil. The formation of bituminous shales is mainly due to slow evaporation of the impregnated oil, vegetable and animal matter in clays before or after being consolidated into shale.

2. The per cent of unsaturates in the distillation cuts of the shale oil showed the unusual phenomenon of two maxima and one minimum. In the first 10 per cent cut the percentage of unsaturates was 32, decreasing to 24 in the 20 to 30 per cent cut, increasing then to 50 per cent unsaturates in the 80 to 90 per cent cut.

3. Benzol, toluol and xylol were present in small amounts in the shale oil recovered.

4. The following phenols have been isolated from shale oil: phenol, (c) (m) cresol, xylenols and guaiacol.

5. Pyrrol, pyridine, picoline, lutidine and parvoline have been found in shale oil.

6. Scotland in 1916 produced 600,000 gallons or 14,260 barrels of gasoline or 0.7 per cent on the total oil recovered from the retorting of 3,500,000 tons of shale. The amount of gasoline produced in the United States in 1916 was 2,500,000,000 gallons. Scotland's production calculates 0.00024 per cent of this amount. The United States exported 110,000,000 gallons of gasoline to the United Kingdom of England in 1917.

7. The oil-shale industry of France is declining, and from government reports France is practically dependent for her oil supplies upon foreign countries.

8. In New South Wales the industry has declined for a number of years, and is at the present time more or less at a standstill. The tons of oil shale retorted dropped from 59,426 in 1895 to 17,425 in 1916.

9. The following tabulation covers the gallons of oil yield per ton of shale retorted in various countries and localities of the United States:

| Shale From                  | Gallons Oil Per Ton | Pounds Ammonium Sulphate Per Ton | Average              |
|-----------------------------|---------------------|----------------------------------|----------------------|
| Utah                        | 25.0                | 13.3                             | 38 samples           |
| Wyoming                     | 16.4                | 15.0                             | 42 samples           |
| Colorado                    | 16.2                | 19.1                             | 51 samples           |
| Present Research (Colorado) | 20.5                | 24.4                             | 2 samples            |
| Scotland                    | 23.0                | 38.0                             | 3,500,000 tons shale |
| Canada                      | 34.9                | 51.3                             | 44 samples           |
| France                      | 20.7                |                                  | 184,030 tons         |
| New South Wales             | (a)                 | (a)                              | 17,425 tons          |
| Black Shale:                |                     |                                  |                      |

(a) Not determined.

In prospectuses, and a number of articles appearing in the oil journals of the country for calculating possible profits from oil shale retorting, the gallons of oil per ton of shale taken, range usually between 42 and 60. But, the above data indicate clearly that an average of shale retorting one-half these values would approximate the gallonage yield of oil per ton of shale retorted. The three states Utah, Wyoming and Colorado have been most carefully studied and the average of 133 samples collected approximate 20 gallons of oil per ton shale retorted.

10. It has been stated that there is sufficient shale in Colorado to produce twenty billion barrels of oil from which two billion barrels of gasoline may be extracted by the ordinary methods of refining. It is certain that no such amount of gasoline is obtainable from twenty billion barrels of oil resulting from retorting Colorado shale. Although nine samples distilled gave approximately 10 per cent of distillate with a volatility similar to gasoline, it is, however, not a gasoline suitable for internal-combustion engines. It is a distillate composed of paraffin hydrocarbons, unsaturated hydrocarbons, nitrogen compounds, sulphur and oxygen compounds. In fact, the complexity of the distillate due to the presence of alkaloidal bases, sulphur compounds and phenols, make it impractical to refine by the ordinary sulphuric acid-caustic soda method prevalent in ordinary refinery practice. Scotland has averaged less than one per cent of marketable gasoline from her shale retorting experience of over fifty years. Can we reasonably expect ten times as much gasoline from the retorting of Colorado shales, than Scotland does from her shales? The experimental evidence shows that the 10 per cent distillate of gasoline volatility from shale oil, will suffer a heavy loss upon refining to produce a marketable gasoline suitable for internal-combustion engines; furthermore, that nothing like 10 per cent or 2,000,000,000 barrels of gasoline will result from the refining of 20,000,000,000 barrels of shale oil from Colorado shale.

11. It is estimated that Southeastern Indiana is underlain with shale-bearing oil which contains 100,000,000,000 barrels of oil.

12. That oil shale is of the highest importance as a potential source of oil is certain. This has been recognized by our government in setting aside shale lands for the use of the navy. The ultimate commercial importance of a shale oil industry in the United States is taken for granted. That it will be an industry requiring very large capital in these days of large capitalization is also positive. At the present time no large shale retorting plants are in existence in the United States, and the cost of installing one is problematical. Furthermore, much experimentation will have to be carried on and the highest technical skill will be required to develop a shale-oil industry in the United States. That shale oil, even with ammonium sulphate as a byproduct can compete at the present time or in the near future with petroleum crude is questionable. For, it must be recognized that new oil fields are being discovered constantly and though many of the known fields of the United States are declining new ones are coming to the fore. Also, Mexico has a potential oil production of known fields of at least 300,000,-

000 barrels a year, and the oil fields of South America have not been tapped as yet. Yet the great oil shale deposits safeguard the economic life of the United States and makes it certain that we will be self-sustaining as to petroleum products during any period of our national life for at least a century.

Department of Chemistry,  
Columbia University, New York City.

**More Chromite Needed.**—The Geological Survey has issued a statement in regard to the chromite situation showing that the present domestic output of chromite is scarcely one-fourth of the quantity needed for war and domestic uses, so that the other three-fourths must be imported. Hitherto most of our imported chromite has come from Rhodesia and New Caledonia, and, notwithstanding the scarcity of ships, much of it still comes from those distant lands. In response to our call for chromite Canada has rendered us most efficient help. In 1916 she sent us 10,930 long tons and in 1917 she more than doubled her shipments of chromite to the United States. The domestic production of chromite in 1916 was about 14,000 long tons, and last spring the prediction was made by Government geologists that in 1917 it would reach 48,000 long tons. According to J. S. Dillon, of the United States Geological Survey, the latest returns indicate that this prophecy has been fulfilled. Most of the known bodies of chromite are small, and those that lie far from lines of transportation are not available for exploitation by the ordinary miner because of the difficulty and expense of getting the ore to the market. Much of the chromite on the Pacific Coast is of low grade, averaging about 40 per cent of chromic oxide, and on that account is of less value than the imported ore, which generally contains 50 per cent or more of chromic oxide. Nicaragua is shipping a small quantity of ore to this country. At Antioquia, Colombia, chromite is reported to be so abundant that it has been used to build the walls of houses. Brazil has valuable deposits several hundred miles northwest of Bahia and may yet become a contributor to our needed supply. Most of the chromite we use is needed in factories in the eastern United States, and on account of the difficulty and expense of long transportation from the western deposits one of our most urgent present needs is to increase the production of chromite in the Atlantic States. The chrome industry of America really began in the eastern States. The mines of Maryland and Pennsylvania once supplied the world's chromite. A recent examination by the Geological Survey of the old chrome mines in Lancaster and Chester counties, Pa., suggests the possibility of successfully concentrating some of the bodies of spotted chrome ore in that region.

Alcohol is being synthesized in commercial quantities from acetylene at Visp, Wallis, Switzerland, according to reports, which are emphasized by the recent article, "Gnomes in Chemistry," *Vossische Zeitung*, by Prof. Dr. K. Arndt. Acetylene, formed by the reaction between calcium carbide and water, is hydrolized in the presence of certain mercury salts yielding acetaldehyde, which is readily reduced by hydrogen in presence of a catalyst (nickel) to alcohol.

Synopsis of Recent Metallurgical and Chemical Literature

Our Fuel Situation, by MR. WILLIAM M. BOOTH, was among the papers read at the meeting of the American Institute of Chemical Engineers at Gorham. Mr. Booth gave a brief account of the transition of the wood fuel days into the present coal age. His table of the British Thermal Units one dollar will buy was very instructive:

|                   | B.t.u. @ \$1 00         |           |
|-------------------|-------------------------|-----------|
| Bituminous coal   | 13,500 b.t.u. per lb.   | 6,750,000 |
|                   | 2,000 lb. @ \$4 00      |           |
| Anthracite.....   | 13,500 b.t.u. per lb.   | 3,375,000 |
|                   | 2,000 lb. @ \$8 00      |           |
| Seasoned hardwood | 4,000 b.t.u. per lb.    | 2,700,000 |
|                   | \$8 00 per 4-ft. cord   |           |
| Natural gas ..... | 1,000 b.t.u. per cu.ft. | 3,333,000 |
|                   | 30c. per 1,000 ft.      |           |
| City gas.....     | 600 b.t.u. per cu.ft.   | 600,000   |
|                   | \$1 00 per 1,000 ft.    |           |
| Crude oil .....   | 19,000 b.t.u. per lb.   | 1,615,000 |
|                   | \$4 00 per bbl.         |           |
| Electricity.....  | 8c. per kw.-hr.         | 4,266     |
|                   | 1c. per kw.-hr.         | 34,128    |
| Alcohol.....      | 95% vol.                | 78,502    |
|                   | \$1 per gal. (6.58 lb.) |           |

WOOD FOR RURAL DISTRICTS—CENTRAL PLANTS FOR CITIES

Mr. Booth gave two tons as an average wood growth rate, per acre of land and thought that in the distant future, the farmer would grow his own fuel off of four or five acres of land. This would not be practical for the cities, for each family would need, on an average, 2000 cu.ft.—this transportation and storage space not being available. Much larger central gas plants will form the solution of the fuel problem in the cities, the overhead expenses of which will be proportionately less as they increase in capacity. Central heating plants can deliver steam for house heating purposes at a saving to the consumer not only of labor but of actual fuel costs in proportion as the plants grow larger, and better conducting pipe lines are provided.

COAL ECONOMY

Because of the comparative cheapness of coal in the past, manufacturers have heretofore never appreciated the future fuel tendencies—higher prices and poorer quality. With transportation and mining capacities unable to supply the present demands interest in the fuel economist is gradually growing. It is to be expected that in the future engineers will have large financial support in their work of attempting to improve the heat yields by the use of better designed equipment, and that preparations will now be forthcoming for the less-coal age. Peat, lignite and shale oil will eventually provide a fair source of material.

At the conclusion of the reading, discussion arose in regard to taking all the available water from Niagara Falls for certain periods of time for electric power generation. Those opposed to such drastic action thought that with the present prices of coal produced power, in all probability no financial gain commensurate with the æsthetic loss could be obtained. Upon a motion made by Mr. J. M. Weiss, it was finally decided to first obtain figure to show the exact relative fuel value of the falls to our coal consumption.

Manganese Steel Rails.—An account which the American Railway Engineering Association has published in Bulletin No. 199 by M. H. WICKHORST, gives the detailed circumstances of various track tests on manganese steel rails, and containing the following conclusions: Manganese steel rails abrade much slower than Bessemer or open-hearth rails on sharp curves, according to the following approximations for curves of 8 or 9 degrees: manganese 0.004 sq.in. per million tons of traffic; open-hearth, 0.012 sq.in.; Bessemer, 0.020 sq.in. The results vary considerably and are probably dependent on the nature of the rolling stock as well as the tonnage. Manganese steel rails become distorted by spreading and drooping of the head more easily than do the others, possibly due to the low elastic limit. Failures of early installations were extremely high, consisting mostly of transverse cracks in the head, but manufacturers claim to have perfected methods for producing a better quality in this respect. Very large deposits of pyrolusite are being developed in Brazil which will supply the demand should it become large.

Alcohol from Sulphite Waste Liquors.—Among the papers read at the June meeting of the American Institute of Chemical Engineers at Gorham, N. H., DR. RALPH H. MCKEE read a paper regarding the fermentation of the sugars in sulphite pulp waste liquor to alcohol without neutralizing the complex magnesia-lime organic acid-sulphite compounds.—Dr. McKee having found that yeast lived and functioned normally in this liquor while a current of air was being blown through. While his work has been limited to the scope of the laboratory, he recommended that the hot liquor from the blow off of the digestors be sprayed in a tower countercurrent to an air current with cooling arrangements so that it would arrive at the fermenting vats at less than 90° F., below which temperature yeast thrives.

ADVANTAGES OF PROCESS

Upon fractional distillation, some sulphur dioxide is present in the alcohol obtained but is readily removed by soda ash. The advantages of this process are claimed to be:

- 1. Saving of equipment.
- 2. No neutralizing with lime.
- 3. Saving in manufacturing costs.

During the subsequent discussion of the paper, MR. H. O. Chute confirmed the fact that yeast was materially aided by air blowing and added that some form of nitrogen and phosphorus had to be added. Mr. Hugh K. Moore asked if NH<sub>4</sub>Cl with the CaSO<sub>4</sub> present would be beneficial. Dr. McKee affirmed this and added that old yeast, hydrolysed at 120° F., made good yeast food. In discussing the form of still adapted to fractionating such a dilute solution of alcohol, Mr. Chute said that a still with a very high tower fractionating column was essential. No data were given regarding the effect of the air in removing or oxidizing the sulphite acids during the passage through the cooling tower, and subsequent fermentation, nor concerning the tendency of the gas sweeping action of the air blowing to carry off the alcohol vapor as it is produced in the vats by the yeast fermentation.

**Manufacture of Phosphoric and Hydrofluosilicic Acids.**—INGENUIN HECHENBLEICKNER, of Charlotte North Carolina, has already patented (1,167,775) improved apparatus for the electric furnace production of  $P_2O_5$ , which delivers the dusty furnace gases to a rotary kiln wherein the phosphate rock and silica are preheated, and thence into a dust catcher where the bulk of the true dust is removed before the temperature has dropped low enough to precipitate the phosphorous pentoxide vapor. This, together with its

Fig. 3

usual content of silicon tetrafluoride, produced by the decomposition of the fluorite ordinarily present as an impurity in the charge, may be absorbed in water, forming a mixture of phosphoric acid ( $H_3PO_4$ ) and hydrofluosilicic acid ( $H_2SiF_6$ ) and which product when utilized in the manufacture of fertilizer may be employed without separation into its components. In case it is desirable to separate these acids, it may be done by cooling the dust-free gas to a point where the  $P_2O_5$  condenses, and then removing this condensate in a Cottrell treater. The  $SiF_4$  is carried on, to be absorbed in the ordinary counter current tower. (1,264,510.) The inventor also patents a variation of the furnace accessories, whereby a waste heat boiler is set close to the furnace, and which catches the true dust, cools the gases to about the condensation temperature of  $P_2O_5$ , and produces steam power. In this case the furnace charge is introduced around the electrodes. (Assigned to the Southern Electro-Chemical Co., 1,264,510; Apr. 30, 1918.)

**Deoxidizer of Titanium and Silicon.**—NAPOLEON G. PETINOT, of New York City, (assigned to United States Alloys Corporation) notes that in the ordinary practice of deoxidation of steel baths with titanium, the oxides produced, being very infusible, remain entrapped in the solidifying metal. He has found that a mixture of silicon and titanium oxides containing 15 per cent of the former has a low melting point, and, therefore, if a deoxidizer containing five times as much titanium as silicon be added to oxidized steel baths, the resulting reaction will produce a fusible slag readily eliminated from the solidifying metal. (1,252,023; Jan. 1, 1918.) For manufacturing this alloy, he uses a proper mixture of pure ingredients such as rutile, quartz, charcoal and steel turnings. This is smelted in an electric furnace with a carbon bottom, and the end of the reduction of the thin layer of iron silicate slag temporarily formed is noted by the extreme instability of furnace operation, accom-

panied by the copious projection of molten metal from the bath. (1,260,037; Mar. 19, 1918.)

**Concentration of Sludge Acid.**—In the refining of petroleum, the oils are always treated with sulphuric acid, the acid and the withdrawn matters then settle out as a heavy sludge. This sludge is ordinarily treated with water, causing a separation into an oily layer called sludge oil, and an aqueous sulphuric acid containing many carbonaceous matters. WM. A. SLATER, of Fort Worth, Texas, finds that the concentration of this waste sludge acid for reuse may be effected by hot air. Instead of forming great volumes of sulphur dioxide by the reaction between the dissolved organic matters and the acid, as is usual when such acid is heated, there is separated granular carbon harmless in subsequent use, and very little oxide is liberated. The inventor attributes these results to "autoxidation" of the organic matters in the hot concentrating acid by the hot air; the sulphur dioxide which tends to form and the organic matter probably oxidizing simultaneously in the manner usual in autoxidations. Fig. 4 shows an arrangement suitable for performing the concentration—the pump 4 forces air through heating coils 1 placed in the flues of nearby stills, and delivers air at about 400 deg. F. to the concentrating tank 8, constructed tightly of acid proof material and having the necessary drains, manholes, thermometers and other auxiliaries. This hot air bubbles through the weak acid to be concentrated, and escapes from the tank, containing some atomized acid, by pipe 16, entering the bottom of the tower 17. Here it ascends against dripping weak acid circulated from tank 22. The air is further scrubbed in the water column 20, and finally escapes. The scrubbing water stored in tank 29 is used to dilute the sludge acid, which latter is the material circulated in tower 17, later to enter concentrator 8. Carbon separates from the acid in circulation through the aeration tower; separating in a rather peculiar form as brittle, round balls. This carbon settles at the bottom of tank 22 and is removed from time to time by cleaning. In

Fig. 4

normal operation the acid in tank 22 is at a temperature of about 200° F. The carbon forming in the concentrator is finely granular and is kept in suspension by the stirring action of the air, and is withdrawn with the concentrated acid. It is found that the temperature required to finish the acid up to 66 deg. Bé. varies somewhat, so that after the temperature reaches say 320 deg. F. it is tested from time to time and withdrawn when the necessary concentration is reached. (Assigned to Gulf Refining Co., 1,262,950; Apr. 23, 1918.)

## A Modern Laboratory for Industrial Research

THE research and testing laboratory of Arthur D. Little, Inc. at Cambridge, Mass., is the fulfillment of plans laid long ago to make effective research easily available to American industry. It is but two and a half minutes' ride by subway from Park Street station in the heart of Boston, to Kendall Square, Cambridge; and from Kendall Square to the laboratory on the Charles River Road is but a four-minute walk. It is an ideal place for work, being at once quiet, sunny and pleasant. The building fronts on the Charles River Basin and beyond it on the further shore is the Back Bay District of Boston, while to the southwest there looms Beacon Hill, the golden dome of the Bulfinch State

LABORATORY IN MARCH, 1918

House and, if tradition is to be trusted, the Sacred Codfish. Along the river road to the west of the laboratory are the monumental buildings of the Massachusetts Institute of Technology.

The first floor of the laboratory is devoted generally to the administrative and accounting department. It contains the offices of the president; the vice presidents, treasurer, secretary and service manager, the head of the commercial department, offices of several engineers, the drafting and accounting rooms and the museum. The museum is an interesting place. Its purpose is to show the relations of raw material to finished products over a wide range of industries. Types of cellulose and the long series of bodies made from it, a great variety of wood products, also a large number of minerals and their metallurgical products are displayed. We have not the space to describe it in detail, but shall content ourselves with saying that it is an enlightening experience for a business man to visit it. Even those with technical training find many surprises. Many maps are in preparation showing the known locations of materials all over the Western Hemisphere.

The second floor is devoted to research. Several of the laboratories are in full operation, while others are not yet completely equipped. Various details of the special equipments change from time to time, according to the nature of the problem in hand.

An interesting feature in regard to problems, as they come in, is that they seem to be addicted to fashions and styles. At present the preponderance of needs seems to be along the lines of applied colloidal chemistry.

On the second floor is a technical library which contains over 30,000 sources of information, indexed by means of over 100,000 cards. This part of the establishment holds the records of over 30 years in industrial research and a great mass of technical reports, bound in manuscript and indexed. It contains also in addition to the many books and sets of scientific periodicals, a large accumulation of clippings from all kinds of sources, filed in envelopes and indexed. The library occupies three rooms and bears a very favorable reputation among librarians because of its arrangement. It has been visited by the school for librarians at Albany, which is spoken of with favor by the guild; and in consulting practise it is found to be in constant use by members of the staff. A very well equipped textile laboratory is also on the second floor.

Analyses and tests are made on the third floor, excepting certain operations, which are carried out in the basement. The general analytical laboratory is at the eastern end of the building and is symmetrically arranged with double parallel rows of hoods made of alberene stone extending east and west on either side of the center. The northern end is devoted to metallurgical analyses, beginning with those of iron and steel. There is an electric furnace with five independent tubes for carbon determinations and a capacity of ten tests per hour. Determinations of copper, zinc, lead, nickel and cobalt are made by electrolysis. The rest of the laboratory is, properly speaking, of a general analytical nature and we shall only attempt to note some of the features observed in passing through. Extractions with water and high-boiling organic solvents are made here. Six oxygen tanks are in constant circulation. There are Freas drying ovens, a Freas incubator, a Hoskins electric furnace and much other highly special as well as general apparatus. Every hood has a gas hot-plate and a steam-bath with ten openings. At the end of each of the four rows of hoods is a section, which may be sealed for poisonous vapors. A water-still supplies the entire laboratory with distilled water through block tin pipes and silver faucets. Balance and volumetric rooms,

THE PAPER MILL

the latter equipped with daylight-lamps, connect with the general analytical laboratory. A separate laboratory with a calorimeter room containing an Emerson gold-lined calorimeter is provided for fuel testing. A

special room is equipped for extractions with inflammable solvents and for the recovery of the same. The optical room contains microscopes of various power and grade, a penetrometer for tars and asphalts, micrometers for determining the thickness of paper and other sheet materials, an ultra violet light apparatus of the same power and design as that used in the U. S. Bureau for Testing Materials, and about a hundred samples of paper of known composition with which com-

COMPLETE RECTIFYING STILL

for the convenience of the janitor) has been turned into a special research laboratory. Still another room is used for storing office files. The boiler room is in the rear. At the eastern end is a complete pulp and paper mill which is a small scale factory in itself. It contains a disc saw for slabs and chips, and two digesters, one rotary and one upright with respective capacities of 350 and 250 pounds of chips. The upright digester is lined with acid resisting brick and is equipped with valves, pressure gages and thermometers similar to those used in commercial practice. For sulphite acid liquors, there is a wooden tank with an agitator and pump. Attached to the digester is a lead-lined blow-off tank. There are two beaters for different kinds of paper stock, one a Jordan engine with a capacity of 100 pounds per hour, two stuff chests complete, and a combination Foudrinier and cylinder paper machine. The widest trimmed sheet which can be run through is 24 inches. The drying end of the machine contains 9 fifteen-inch driers with 32-inch face, and a calendar stack of 7 rolls of 7 inches diameter. Power is furnished by a 15-hp. motor for the beaters and the Jordan; a 5-hp. motor is attached to the constant speed end of the paper machine; while a 6-hp. variable speed motor provides power for the rest of it. One horsepower motors are used for agitators, pumps, etc. It really is a complete pulp and paper mill in which practically any kind of pulp or paper can be made.

At the western end of the basement is a considerable array of chemical apparatus for other work on a small factory scale. This includes tanks, vats, a diffusion battery, a luminous fractional tower and still and

parative fiber tests are made. For this purpose the samples are treated with the zinc chloride iodine stain, which colors ground wood pulp yellow, rag pulp red, and that of sulphite blue. Other fibers have their peculiar shapes and structural markings by which they are recognized under the microscope. Samples of fiber to be tested are checked against those of known content and the ratios are very closely approximated. Here and in the adjoining room for physical determination is a photomicrographic apparatus, a projectoscope, which is of great convenience for bringing the attention of several observers at once upon a problem, a polariscope, a Schopper paper tensile strength machine, a Schopper folder for measuring the resistance of paper to folding (two German instruments that should be made hereafter in America), Mullin strength testers which measure bursting strength in pound per square inch, Lloyd's hygrodeik (Taylor) that gives relative humidity to temperature for the control of tests, a privately designed apparatus for determining resistance of paper carton, etc., to bending, another original apparatus for determining the resistance of paper to tearing, a Perkins stretch tester and an Ives colorimeter.

The basement contains a room for crushing and grinding various substances. The mill for sampling coal is in a separate room, also in the basement. In another room is a rubber grinding machine; here are also located an emery wheel for polishing steel samples, a drill press for cutting them and a physical testing apparatus of 10,000 lb. capacity. The main stock room serves as a general store from which local stores of supplies on the second and third floors are furnished by means of a dumb-waiter. In the basement is a sample room, in which the original samples are kept for required periods. Another room (originally designed

GENERAL ANALYTICAL LABORATORY

other equipment. It is, like the paper mill, provided with an adjoining control laboratory.

A feature of great convenience is the relation of the general analytical to the research laboratories. Those engaged in research have their results tested and checked as often as they desire, which is naturally done far more expeditiously and accurately than if each research chemist had to rig up apparatus and make his own analyses. It was quite a venture to build this large establishment with such a great capacity, especially since it is a development to which industry has not as yet, in many respects, fully arrived.

## Book Reviews

**GENERAL CHEMISTRY.** By *Hamilton P. Cady, Ph.D.* Octavo, (14 x 20 cm.), xiv + 522 pages, 73 illustrations; price, \$2.25. McGraw-Hill Book Company, Inc.: New York. Hill Publishing Co., Ltd.: London.

This is an elementary book, an abridgment and simplification of the author's earlier book entitled "Inorganic Chemistry," intended for a shorter course. There is a large amount of material in the book, very well arranged. Chemical facts are presented in large numbers before discussions of chemical theories are introduced as attempted explanations of the facts. The text is very reliable, and the industrial information scattered through it is particularly well chosen and up to date (with the exception of the manufacture of boron by Weintraub's method, and of sodium by Von Kugelgen's process). Here and there a generalization is made too broad or a dictum laid down too tight, which is really serious because it misinforms the student and blunts the development of his scientific acumen. Such a case is the statement (p. 6) that it is a law that "if two bodies agree exactly in some few of their essential properties they will agree exactly in all and are composed of the same substance"; another (p. 27), that "whenever two or more substances combine to form another substance, they do so in a perfectly fixed and invariable ratio by weight." When the author revises this excellent book, he should carefully excise these illogical statements and imperfect generalizations. Otherwise there is hardly anything but praise to be expressed for the clearness and accuracy of presentation and method shown on almost every page of the book.

\* \* \*

**VAN NOSTRAND'S CHEMICAL ANNUAL.** By *John C. Olsen.* Fourth Issue, 778 pages. Price \$3.00. New York: D. Van Nostrand Company.

Since the 1913 issue the author has revised and added new material. The present volume has 161 tables of which 48 are new. The most authoritative chemical data on the physical constants of inorganic and organic compounds, alkaloids, essential oils, oils, fats, waxes, lubricating oils and gases are systematically treated. The standard tables of specific gravities of acids, bases, solutions and solvents are arranged in very legible form. The vapor tension of water and mercury, the equivalents of weights and measures, thermochemical data and the usual stoichiometrical and analytical data have highly satisfactory treatment. The special feature of this high grade book of tables is the chapter on stoichiometry by Prof. R. H. Ashley, in which a number of type problems are set and solved. These will be of great aid to many in becoming familiar with the application of the tables. A good catalog of technical books is included.

\* \* \*

**LABORATORY MANUAL OF BITUMINOUS MATERIALS.** By *Prévost Hubbard.* Octavo (14 x 23 cm.), xi + 153 pages, 39 illustrations; price, \$1.50. New York: John Wiley & Sons, Inc. London: Chapman & Hall, Ltd.

Intended as a laboratory guide for students of highway engineering, this treatise not only develops the abstract technique of the laboratory, but also deals with the interpretation of the results of tests, such as the suitability of the materials for specific purposes and control of uniformity of the materials in question. The testing is limited to the bituminous materials used in highway construction, and does not extend to the other materials, such as stone, gravel, sand, filler, wood, etc. used with the bitumen. The scope of the work is therefore very limited but in its field it is most excellently and practically written. It is too advanced and too specialized for the ordinary civil engineering student, but will be of great value to the graduate student specializing in highway construction and for all road-building specialists. One sole criticism is the use of "burning point" in place of "ignition point."

**THE CHEMIST'S POCKET MANUAL.** By *Richard K. Meade.* 530 pages. Price \$3.50. Easton, Pa.: Chemical Publishing Company.

The manual is a very condensed book printed in small type, covering a very wide scope in a brief manner. A table of contents should have been included as it would prove of great aid in familiarizing the readers of the book with the material. The 180 pages of technical analysis will prove valuable to those who do not have access to larger works or want a resumé on this subject. The tables do not equal other recent publications in the pure chemical field but treat many subjects not ordinarily found in these, a small amount of applied physics being included.

## Personal

**MR. L. G. E. BIGNELL**, formerly sales manager of the Denver office of Sutton, Steele & Steele, Inc., has been placed in charge of sales for the same company with offices in Dallas, Texas.

**MR. G. GRUNBERG** has recently severed his connection with the American Scientific Instrument Co. and has established his own business under the name of Scientific Utilities Company, Inc., which is located at 843 E. 10 St., N. Y. C.

**DR. A. E. KENNELLY**, acting head of the Department of Electrical Engineering at the Massachusetts Institute of Technology, has been called to Washington for special work with the Signal Corps. He expects to return to the Institute in the fall.

**MR. HENDERSON W. KNOTT**, formerly general manager of the Morgan Crucible Company of New York City, has been appointed by the United States Fuel Administration to manage the field force of engineers and inspectors who are at work among the power plants of the country. He will carry out a campaign of instruction and inspection to bring the use of fuel for the production of power to the highest possible efficiency and economy.

**DR. ARTHUR D. LITTLE**, of Arthur D. Little, Inc., Cambridge, was conferred the honorary degree of Doctor of Chemistry by the University of Pittsburgh at the commencement exercises on May 31, 1918.

**MR. A. NIEDERMAYER**, for many years connected with the Worthington Pump and Machinery Corporation, more recently as Works Manager of the Snow-Holly Works of that corporation, at Buffalo, N. Y., resigned on May 31 to devote his entire time to enterprises of his own.

**MR. DWIGHT P. ROBINSON** and **MR. JOHN W. HALLOWELL** retired from the firm of Stone & Webster on July 1, and the business will be continued by the remaining partners MESSRS. CHARLES A. STONE, EDWIN S. WEBSTER, RUSSELL ROBB, and HENRY G. BRADLEE. Mr. Robinson has been with Stone & Webster since 1893, from 1908 as president of the Stone & Webster Engineering Corporation and a member of the firm since 1912. Mr. Hallowell has been with Stone & Webster since 1901 and a member of the firm since 1912. Since May 1917, he has been in Washington with Mr. Hoover as a member of the United States Food Administration and expects to continue in that work for the duration of the war.

**MR. CHARLES B. SEEM** has become actively connected with the Electric Furnace Company in the capacity of sales engineer. He was formerly with Perin & Marshall, Consulting Engineers.

**DR. ALFRED STANSFIELD**, Professor of Metallurgy of McGill University, was recently in San Francisco conferring with officials of the Noble Electric Company. Dr. Stansfield has been retained by the provincial government of British Columbia to report upon the possibilities of establishing an electric iron and steel industry in that region.

THE UNITED STATES FUEL ADMINISTRATION announces the appointment of administrative engineers as follows: THOMAS R. BROWN, Pittsburgh; for the western half of

Pennsylvania. He was formerly special engineer with the Westinghouse Air Brake Company. GEORGE R. HENDERSON, Philadelphia; for the eastern half of Pennsylvania. He was formerly consulting engineer with the Baldwin Locomotive Works. EDWARD N. TRUMP, New York; for the state of New York. He has been the vice president of the Solvay Process Company. W. R. C. CORSON, Hartford; for New England. He has been actively engaged in practice as a consulting engineer.

MR. H. S. WETZEL, formerly chief chemical engineer of the Pittsburgh-Butte Coal Co., has resigned to accept a position with the National Carbon Company of Niagara Falls, N. Y.

## Obituary

MR. ROBERT BROWN CARNAHAN, JR., vice president of The American Rolling Mill Co., was killed in an accident on June 22, 1918. After graduating from the University of Pittsburgh in 1891, Mr. Carnahan was actively associated with the Dewees-Wood Company at McKeesport, Pa. from 1893 to 1899, when he went to the Homestead Works of the Carnegie Steel Co., soon after which he went into the present central works of The American Rolling Mill Co. as chief chemist and open hearth superintendent. It was under Mr. Carnahan's direction that Armco American Ingot Iron was developed. Mr. Carnahan was a member of The American Iron and Steel Institute, The American Institute of Mining Engineers and The American Society For Testing Materials. His alma mater conferred the honorary degree of Doctor of Science upon him in 1912.

DR. EDGAR MARBURG, secretary-treasurer of The American Society for Testing Materials, and professor of Civil Engineering in the University of Pennsylvania, died June 27, 1918, the news of his death being received during the twenty-first meeting of the Society.

## Current Market Reports

### Non-Ferrous Metal Market

**Monday, July 8:**—Prices have a tendency to rise due to the 25% freight rate increase.

**Aluminium:**—The government price is 30c. a pound f.o.b. plant in 50-ton lots, 33.1c. down to 15-ton lots, and 33.2c. in lots down to 1 ton, 40c. to 45c. for smaller lots.

**Antimony:**—Demand is quiet but large orders are expected. Spot antimony, duty paid, is quoted at 13c. to 13½c.

**Chrome:**—Producers have established a schedule on the basis of \$1.30 per unit ore; some 40% ore has sold for \$1.50 per unit.

**Copper:**—The price has been advanced to 26c., an increase of 2½c., about one-half of which is to go to an increased refinery rate.

**Lead:**—The basic fixed price at East St. Louis is 7½c. New York is short and prices vary from 8.05c. to 8.25c.

**Manganese:**—Variable ton unit scale price, 40 per cent \$1.10, 50 per cent \$1.20. For full specifications see Metallurgical and Chemical Engineering, page 629, June 15.

**Manganese:**—Variable ton unit scale price: 40%, \$1.10; 50%, \$1.20. For full specifications see METALLURGICAL AND CHEMICAL ENGINEERING, page 629, June 15.

**Molybdenum:**—Quoted at \$1.25 per pound for 90% molybdenum sulphide.

**Silver:**—Sixty-four million silver dollars have been melted into bullion by the U. S. Treasury, for export to India. The Treasury still holds 426,000,000 silver dollars, against which \$390,000,000 silver certificates are outstanding. Silver is quoted at 99% c. per troy ounce.

**Spelter:**—Buying not heavy. Prime western is quoted at New York at 8.67½c. to 8.87½c. for July; at East St. Louis, 8½c. to 8% c., futures to October 8.55c. to 8.80c.

**Tin:**—Conservative buying. At Coast, Banca is offered at 91c. At New York, Lamb and Flagg at 94c., Straits for August shipment at 87½c. Large consumers importing direct.

**Tungsten:**—The highest grade material containing no tin, no copper, low manganese and over 70% WO<sub>3</sub>, has brought \$24.00 per ton unit. Impure material has sold as low as 95c. per pound WO<sub>3</sub> contained.

|                        |          |        |
|------------------------|----------|--------|
| Bismuth .....          | \$3.50   |        |

| Mexican (75 lb.) ..    | \$118.00 |        |

### The Iron and Steel Market

While the stiff freight rate advance of June 25 bears very heavily upon the merchant blast furnaces, particularly as the advance of 45 cents a ton in Lake Superior ore allowed by the War Industries Board passes the rate advance on Lake Superior ore on to the blast furnaces, the chief complaint of blast furnaces that there is too little margin between costs and the permissible maximum selling prices, or no margin at all, comes from furnaces in Tennessee and Virginia, and arises largely from quite unsatisfactory labor performance. The effect upon negro labor of successive wage advances has been particularly unfortunate, as to make living expenses it is quite unnecessary to work full time, and the men sometimes work as few as two days a week, interfering sadly with full operation, while performance when on duty is far below standard. There are various other difficulties, but the matter of labor presents the most serious problem. While a few of the furnaces have been advocating a higher selling price, it is the common opinion that the matter must be approached from some other angle. The American Pig Iron Association has held two general meetings on the subject, the details of the discussion not being made public.

### PROFITS AND TAXATION

The steel manufacturers as a whole are well satisfied with the price situation, as with few exceptions the allowed prices afford very comfortable profits. The manufacturers are concerned chiefly with production, being anxious to have full output in order to meet fully all the desires of the Government and incidentally to keep down costs, which mounted very seriously last January and February, with the average of 55 to 60 per cent operation which obtained in those months.

There has been a little criticism in some quarters of the report the Federal Trade Commission recently made to the Senate as to profits in various industries, and it is evident that the critics did not digest the report or they would have been able to find no reasonable fault with the references to the iron and steel industry. The Senate called for the report, by resolution, for the double purpose of securing information that would be helpful in the taxation program and of receiving light on how profiteering might be regulated by law. As to the latter phase of the general inquiry the Federal Trade Commission could make no reference in the case of iron and steel, for the reason that all iron and steel prices are controlled strictly by the War Industries Board, under approval of the President, and the regulating authorities are well satisfied with the situation. The Federal Trade Commission, moreover, has an important voice in the settling of iron and steel prices, the War Industries Board depending largely upon its findings as to costs, and also upon its judgment. As a matter of fact the report in question made absolutely no attempt to criticize the existing iron and steel prices. The report did show that the industry as a whole is making very large profits, but as Congress is seeking profits for the purpose of taxing them, with an eight billion dollar revenue program before it, the reference was decidedly fitting. The report did not criticize the iron and steel industry in any respect. The "meat trust" on the other hand was scored severely, while the accounting and other methods employed by some industries that are allowed a margin above cost, particularly the flour milling industry, were severely criticized. At-

tention was directed to the fact that in industry in general there are many instances of wide divergencies in cost, whereby a given price may afford one manufacturer a small profit and another a large profit, this being distinctly suggestive of the desirability of a general policy of having relatively high prices and of taxing excess profits very heavily. On the whole the report furnishes some ground for expectation that there will not be much effort made to reduce iron and steel prices, while excess profits will be heavily taxed.

#### LABOR AND PRODUCTION

It is becoming increasingly clear that in the matter of production it is not so much a question of the number of workmen available as a whole as it is a question of their performance. The Government is insisting that after August 1 employers engaged in war work shall recruit labor through no channel but the federal employment offices organized by the Department of Labor. There has been much waste of labor through labor recruiting methods which may have benefited the employers who practiced them, but certainly injured other employers. The iron and steel producers feel that they have suffered much more than they have benefited from the recruiting of labor by the payment of bonuses, and other unusual methods, and hopes for better conditions when the federal employment system is made the sole means of employing labor.

#### SOLUTION OF PROBLEM

The American Sheet & Tin Plate Company has put into operation a system of its own devising for stimulating activity among its employes, and finds even the first experience in this connection very satisfactory, definite and valuable results being observed within the first fortnight of the system's application. The first operation was to post notices at all the company's plants, 13 sheet plants and 14 tin plate plants, to the effect that all employes would be solicited to sign a pledge for 100 per cent. efficiency. The men became interested at once, and began calling for the pledge cards, which were being prepared as rapidly as possible. Each card carries the pledge in English and in some foreign language. The workman signs the pledge card and returns it to the manager. A record is made and the signed pledge is returned to the man, who knows that the company has a record of his having signed the pledge, which obligates him: (1) Not to absent himself from work except when absolutely necessary; (2) to work faithfully when on duty; (3) to make every effort to induce his fellow workmen to do likewise. There is a series of four buttons, each with the inscription "100 per cent efficiency man," white upon signing the pledge, red upon keeping it for 30 days, blue for 60 days and red, white and blue for 90 days, the 90-day service involving also a "service certificate." The idea took hold so well that men began forming "efficiency clubs" providing a fine of \$1, to go to the Red Cross, for avoidable absence. The company employs men speaking 59 languages, only a fraction of this number being represented at any one plant. A record of attendance at work is kept, quite apart from the payroll, and each case of absence is investigated, unavoidable absences being excused.

#### DISTRIBUTION

Supplies of merchant pig iron and of steel are in the main not sufficient to cover entirely the preference list, after direct and indirect government orders are satisfied, and as a result scarcely any material is being distributed to the general trade, not accorded any preference. The preference uses, however, are so numerous that there are but few requirements of a general commercial character not covered. Buyers not entitled to preference, moreover, have some stocks of material and supplies may become available for them before present stocks are exhausted. The war activities are in many cases receiving more material than is currently consumed, this being in accordance with the desire of the Director of Steel Supply, that surpluses be accumulated, particularly in connection with shipbuilding and shell manufacture, to provide against possible curtailment in production and shipments next winter. The

manufacture and consumption of steel for war purposes is proceeding in a very satisfactory manner.

#### STRUCTURAL STEELS.

|                                            |               |
|--------------------------------------------|---------------|
| Tank Plates, Sheets, etc., per ton         | 70.00—80.00   |
| Beams, Channels, Z's, T's, L's, wire, etc. | 65.00—85.00   |
| Rivets, Spikes, Rails, etc.                | 88.00—100.00  |
| Tin Plate, Tern, etc.                      | 150.00—155.00 |
| Galvanized Sheets, etc.                    | 104.00—135.00 |

#### Chemical Market

**HEAVY CHEMICALS:**—In general the period of the last two weeks has been very quiet but marked by some little activity in caustic soda which is considered the barometer of conditions of the present. There developed considerable call for sodium sulphide, saccharine and calcium carbide but as is usual under a heavy inquiry, stocks were very meagre.

**Trisodium Phosphate:** For material in carload lots interests are quoting 5c per pound f.o.b. New York with smaller quantities available at 5½c. Inquiry was not active and although stocks are not heavy there apparently is confidence in ability to supply the demand. There is also material at hand available for export.

**Caustic Soda:** The situation is causing considerable comment and the unusually quiet conditions prevailing do not seem to indicate any improvement for the near future at least. Material rolling to New York is thought to amount to a rather important tonnage and buyers are seemingly fully aware of this situation and are awaiting developments before attempting to enter the market. Some stocks were held as low as 3.80 and 3.90 rolling, but generally these were brands not in particular favor. For standard brands such as 76 from 4.15 to 4.30 is being asked ex-store New York.

**Soda Ash:** The dense material has been very hard to locate but has been in strong demand for Western shipment with prices quoted at 3.80 f.o.b. Western works. The light ash is being offered at from 2.10 to 2.15 in bags, spot New York and at from 2.80 to 2.85 in barrels and up to 2.90 in some instances.

**Sulphuric Acid:** The notable feature on this item and of great moment to the trade was the definite announcement from Washington that the War Trade Board has definitely fixed the maximum trading levels for acids. The 66 degree material is fixed at \$28.00 f.o.b. works in sellers tanks. The 60 degree material is to sell at a maximum level of \$18.00 same basis. The basis for fuming acid, 20% oleum is \$32.00 per ton. In carboy carload lots one-half cent per pound extra is allowed and in carboys less than carloads three quarters of a cent per pound extra is allowed. In drums any quantity one-half cent per pound extra is allowed. So far the trade is without more definite advices and until the ruling in detail is explained matters will be rather complicated. It has been made plain however that the price setting is not to be retroactive and that contracts now in effect or those which have not yet been completed, will not be affected unfavorably.

**Nitric Acid:** Forty-two degrees Baumé 8½c per pound, f.o.b. manufacturers' works in carboys. Other strengths of nitric acid based upon the above prices are as follows:

|             |                  |                    |
|-------------|------------------|--------------------|
| Nitric Acid | 36 degrees Baume | \$0.0650 per pound |
| Nitric Acid | 38 degrees Baume | .0715 per pound    |
| Nitric Acid | 40 degrees Baume | .0775 per pound    |
| Nitric Acid | 42 degrees Baume | .0850 per pound    |
| Nitric Acid | 43 degrees Baume | .0890 per pound    |

A schedule of prices on mixed acids is being prepared and will be published later.

The above maximum prices are agreed upon for the public, as well as for Government purchases. It is understood and agreed that any deliveries made after September 30th will be subject to any revision in price which the Government may make for deliveries after that date. The above prices do not in any way interfere with contracts now in effect and which have not yet been completed. It is understood that carboys are to be invoiced as shipments are made, and credit issued when returned in good order.

**Pernmanganate of Potash:** Prices asked for spot material are holding steady although the market has been quiet, in general with most other items. The U. S. P. material is ranging from 2.50 to 2.60 per pound and about 2.25 to

2.30 for the technical grade. For the U. S. P. on contract there is concession to the extent of from ten to twenty-five cents.

**Sal Ammoniac:** With the diminishing of supplies the tendency has been for the raising of the asking price and it has been noted that a considerable quantity of the gray material has been passed at 22c, rolling. There has been a very steady demand.

**COAL TAR PRODUCTS:** The general tendency in this market has been toward an advance in prices although things have been rather quiet particularly in the latter part of the two weeks period owing to the holiday. One of the most notable occurrences was the direct reversal of relations between the two saccharines.

**Phenol:** There are many conflicting rumors concerning supply, demand, exports and imports and also with regard to governmental attitude; but as near as it is possible at present to gain them the facts appear to be that there is a very small unsold or uncontracted-for supply of phenol available today. The demand has been very good; export licenses are continuing to be granted and there is some mystification as to the reasons for the importations of the English phenol, arrivals of which have been reported as there is for even the offerings which are known to have been made, because of the undoubted requirements of the British Government itself for this product. The question remains unanswered as does also the one with regard to exportations from this country when it is known that although the U. S. Government has contracted for all requirements up to date they are placing large contracts for future deliveries of millions of pounds to take care of estimated monthly needs and still are not confident that the production will keep pace with the growing need for and production of picric acid. It is felt however that such government orders do not have a direct affect upon the resale market. Sales have been made of large quantities at 44c which is very close to that which the English material would bring with all duties paid. General quotations on resale continue at, and the market is judged to be from, 45 to 48c.

**Paranitraniline:** Inquiry on this item has been very good but material is said to be scarce and holders few. Those who have material to offer are doing so in very small quantities. Prices show a tendency to advance as some holders are asking ten cents more on the small lots offered than was asked a few days ago. Actual sales are reported of five barrel quantities at 1.85.

**H-Acid:** Production is centered in a few hands and the demand has evidently absorbed the supplies for July as factors are reticent about quoting on material for earlier than August shipment. The prices quoted show a tendency toward a rise as 2.60 is now the lowest heard and in some directions there is refusal to accept less than 2.75. For the highest grades however no quotations have yet been heard in excess of 3.00.

**Saccharines:** The soluble material has been in extraordinary demand with holders hard to locate. Relations as to price and demand have reversed themselves as between the two grades in that the soluble has actually passed at 29.00 and 30.00 with the insoluble now at from 22.00 to 23.00.

**Dinitrophenol:** Quotations on material for shipment f.o.b. works run from 55 to 60c according to quantity. Supplies are said to be available to cover all needs at least in the present state of the market as the inquiry for this product is but fair and actual sales but few.

**Monochlorbenzol:** Some factors are completely sold up on stocks for the balance of the year on contract but from certain sources plenty of the product is obtainable at the prices of from 17 to 19c according to quantity desired. Inquiry however has been slow.

**Benzoate of Soda:** Prices for the soda continue to be quoted at from 3.00 to 3.25 and for the acid at from 3.45 to 3.70, however, it is rumored that both of these products are to be advanced in the near future as the prices at which they have been holding are so close to manufacturing cost as to not permit of profitable business on present demands.

## General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET, JULY 8, 1918

|                                                 |         |               |         |
|-------------------------------------------------|---------|---------------|---------|
| Acetic anhydride                                | lb.     | 1 60          | 1.85    |
| Acetone, drums                                  | lb.     | Nominal       |         |
| Acid, acetic, 28 per cent                       | lb.     | Nominal       |         |
| Acetic, 56 per cent                             | lb.     | Nominal       |         |
| Acetic, glacial, 99 1/2 per cent, carboys       | lb.     | Nominal       |         |
| Boric crystals                                  | lb.     | 184           | .15     |
| Citric crystals                                 | lb.     | 82            | .88     |
| Hydrochloric, C. P.                             | lb.     | Nominal       |         |
| Hydrochloric, 20 deg.                           | lb.     | .02           | .02 1/2 |
| Hydrochloric, conc., 22 deg.                    | lb.     | .02 1/2       | .03 1/2 |
| Hydrofluoric, 30 per cent in barrels            | lb.     | .06           | .06 1/2 |
| Lactic, 44 per cent                             | lb.     | .15           | .16     |
| Lactic, 22 per cent                             | lb.     | .06           | .07     |
| Molybdenic, C. P.                               | lb.     | 6 90          | 7.40    |
| Nitric, 36 deg.                                 | lb.     | Nominal       |         |
| Nitric, 42 deg.                                 | lb.     | .03 1/2       | .10     |
| Oxalic, crystals                                | lb.     | .08           | .45     |
| Phosphoric, 47-50 per cent paste                | lb.     | .08           | .10     |
| Phosphoric, ref. 50 per cent                    | lb.     | .33           | .40     |
| Picric                                          | lb.     | Nominal       |         |
| Pyrogallol, resublimed                          | lb.     | 3 10          | 3.15    |
| Sulphuric, 60 deg.                              | ton     | Nominal       |         |
| Sulphuric, 66 deg.                              | ton     | Nominal       |         |
| Sulphuric, oleum (Fuming), tank cars            | ton     | Nominal       |         |
| Tannic, U. S. P., bulk                          | lb.     | 1 40          | 1.45    |
| Tartaric crystals                               | lb.     | .86           | .89     |
| Tungstic, per lb. of W                          | lb.     | 1 70          | 1.75    |
| Alcohol, sugar cane, 188 proof                  | gal.    | 4 89          | 4.90    |
| Alcohol, wood, 95 per cent                      | gal.    | .90 1/2       | .91     |
| Alcohol, denatured, 180 proof                   | gal.    | .67           | .68     |
| Alum, ammonia lump                              | lb.     | .04           | .04 1/2 |
| Alum, chrome ammonium                           | lb.     | .18           | .19     |
| Alum, chrome potassum                           | lb.     | .20           | .21     |
| Alum, chrome sodium                             | lb.     | .12 1/2       | .13     |
| Alum, potash lump                               | lb.     | .08           | .09     |
| Aluminium sulphate, technical                   | lb.     | .02 1/2       | .03     |
| Aluminium sulphate, iron free                   | lb.     | .03           | .04     |
| Ammonia aqua, 26 deg., carboys                  | lb.     | (Fixed Price) |         |
| Ammonia, anhydrous                              | lb.     | 15            | Nominal |
| Ammonium carbonate                              | lb.     | 15            | .16     |
| Ammonium nitrate                                | lb.     | (Fixed Price) | .15     |
| Ammonium sulphate domestic                      | lb.     | .07 1/2       | .08     |
| Amyl acetate                                    | gal.    | 5 15          | 5.25    |
| Arsenic, white                                  | lb.     | .04 1/2       | .17     |
| Arsenic, red                                    | lb.     | .65           | .70     |
| Barium carbonate, 99 per cent                   | ton     | 80.00         | 90.00   |
| Barium carbonate, 97-98 per cent                | ton     | 65.00         | 67.00   |
| Barium chloride                                 | ton     | 65.00         | 70.00   |
| Barium sulphate (Blanc Fixe, Dry)               | lb.     | .04 1/2       | .05     |
| Barium nitrate                                  | lb.     | .10           | .11     |
| Barium peroxide, 70-75 per cent                 | lb.     | .30           | .32     |
| Bleaching powder, 35 per cent chlorine          | lb.     | .02           | .03     |
| Borax, crystals, sacks                          | lb.     | .07 1/2       | .08 1/2 |
| Brimstone, crude                                | ton     | Nominal       |         |
| Bromine, technical                              | lb.     | .75           | Nominal |
| Calcium, acetate, crude                         | lb.     | Nominal       |         |
| Calcium, carbide                                | lb.     | .15           | .16     |
| Calcium chloride, 70-75 per cent, fused, lump   | ton     | 22.00         | 24.00   |
| Calcium peroxide                                | lb.     | 1 60          | 1.70    |
| Calcium phosphate                               | lb.     | .22           | .23     |
| Calcium sulphate 98-99 per cent                 | lb.     | .09           | .09 1/2 |
| Carbon bisulphide                               | lb.     | .08 1/2       | .09     |
| Carbon tetrachloride, drums                     | lb.     | 1 10          | 1.18    |
| Carbonyl chloride (phosgene)                    | lb.     | 1 10          | 1.50    |
| Caustic potash, 88-92 per cent                  | lb.     | 4 00          | 4.25    |
| Caustic soda, 76 per cent                       | 100 lb. | 4 00          | 4.25    |
| Chlorine, liquid                                | lb.     | (Fixed Price) | .07 1/2 |
| Cobalt oxide                                    | lb.     | 1 60          | 1.65    |
| Copperas                                        | lb.     | .01 1/2       | .32     |
| Copper carbonate                                | lb.     | .75           | .78     |
| Copper cyanide                                  | lb.     | .08 1/2       | .09 1/2 |
| Copper sulphate, 99 per cent, large crystals    | lb.     | .77           | .78     |
| Cream of tartar, crystals                       | lb.     | 3 62 1/2      | 3.90    |
| Epsom salt, bulk, U. S. P.                      | lb.     | 16 1/2        | 17 1/2  |
| Formaldehyde, 40 per cent                       | 100 lb. | 1 50          | 1.75    |
| Glauber's salt                                  | lb.     | .62           | .65     |
| Glycerine, bulk, C. P.                          | lb.     | 4 25          | 4.30    |
| Iodine, resublimed                              | lb.     | .13           | .15     |
| Iron oxide                                      | lb.     | .17           | .18     |
| Lead acetate, white crystals                    | lb.     | .15           | .18     |
| Lead arsenate (Paste)                           | lb.     | .15           | Nominal |
| Lead nitrate                                    | lb.     | Nominal       |         |
| Litharge, American                              | lb.     | 1 01          | 1.23    |
| Lithium carbonate                               | lb.     | 1 50          | 2.00    |
| Manganese dioxide, U. S. P.                     | lb.     | .70           | .75     |
| Magnesium carbonate, technical                  | lb.     | .21           | .23     |
| Nickel salt, single                             | lb.     | .14           | .15     |
| Nickel salt, double                             | lb.     | .12           | .14     |
| Phosgene, gas, Carbonyl chloride                | lb.     | 1 20          | 1.30    |
| Phosphorus, red                                 | lb.     | 1 00          | 1.25    |
| Phosphorus, yellow                              | lb.     | .46           | .47     |
| Potassium bichromate                            | lb.     | 3 15          | 3.50    |
| Potassium bromide, red                          | lb.     | 40            | 50      |
| Potassium carbonate calcined, 85-90 per cent    | lb.     | 38            | 40      |
| Potassium chlorate, crystals                    | lb.     | Nominal       |         |
| Potassium cyanide, 98-99 per cent               | lb.     | 3 75          | 3.80    |
| Potassium iodide                                | ton     | 300 00        | 350 00  |
| Potassium muriate 80-85 p. c. basis of 80 p. c. | lb.     | .27           | .31     |
| Potassium nitrate                               | lb.     | 2 50          | 3.65    |
| Potassium permanganate (U. S. P.)               | lb.     | 1 80          | 2.90    |
| Potassium prussiate, red                        | lb.     | 1 10          | 1.20    |
| Potassium prussiate, yellow                     | ton     | Nominal       |         |
| Potassium sulphate, 90-95 p. c. basis 90 p. c.  | lb.     | 44 1/2        | 46      |
| Rochelle salt                                   | lb.     | .22           | .23     |
| Salammoniac, gray gran                          | lb.     | .20           | .21     |
| Salammoniac, white gran                         | lb.     | 1 35          | 1.40    |
| Salt soda                                       | 100 lb. | 30 00         | 35 00   |
| Salt cake                                       | ton     | 30 00         | 35 00   |
| Silver cyanide, based on market price of silver | oz.     | .62 1/2       | .63     |
| Silver nitrate                                  | 100 lb. | 2 10          | 2.15    |
| Soda ash, 56 per cent, light, flat (bags)       | 100 lb. | 3 65          | 4.00    |
| Soda ash, 56 per cent, dense, flat              | lb.     | Nominal       |         |
| Sodium bicarbonate, domestic                    | lb.     | .03           | .03 1/2 |
| Sodium bicarbonate, English                     | lb.     | .27 1/2       | .29     |

| Sodium molybdate, per lb. of Mo        | lb.     | 2 50 | —       | —    |
| Sodium nitrate, 95 per cent            | 100 lb. | 28   | Nominal | 30   |
| Sodium nitrite                         | lb.     | 35   | —       | 45   |
| Sodium peroxide                        | lb.     | 04   | —       | 05   |
| Sodium phosphate                       | lb.     | 60   | —       | 63   |
| Sodium prussiate, yellow               | lb.     | 06   | Nominal | —    |
| Sodium silicate, liquid (60 deg.)      | lb.     | —    | Nominal | —    |
| Sodium sulphide, 30 per cent, crystals | 100 lb. | —    | Nominal | —    |
| Sodium sulphate, 60 per cent, fused    | 100 lb. | —    | Nominal | —    |
| Sodium sulphate                        | lb.     | 25   | —       | 35   |
| Strontium nitrate                      | lb.     | 06   | —       | 063  |
| Sulphur chloride, drums                | lb.     | 15   | —       | 40   |
| Sulphur dioxide, liquid, in cylinders  | 100 lb. | 4 05 | —       | 4 60 |
| Sulphur, flowers, sublimed             | 100 lb. | 3 70 | —       | 3 85 |
| Sulphur, roll                          | ton     | —    | Nominal | —    |
| Sulphur, crude                         | lb.     | 28   | —       | 29   |
| Tin bichloride, 50 deg.                | lb.     | 1 00 | —       | 1 25 |
| Tin oxide                              | lb.     | 22   | —       | 15   |
| Zinc carbonate                         | lb.     | 15   | —       | 18   |
| Zinc chloride                          | lb.     | —    | Nominal | —    |
| Zinc cyanide                           | lb.     | 14   | —       | 16   |
| Zinc dust, 350 mesh                    | lb.     | 13   | —       | 14   |
| Zinc oxide, American process XX        | lb.     | 05   | —       | 06   |
| Zinc sulphate                          | lb.     | —    | —       | —    |

### Coal Tar Products (Crude)

|                                        |      |      |               |       |
|----------------------------------------|------|------|---------------|-------|
| Benzol, pure, water white              | gal. | 23   | —             | 28    |
| Benzol, 90 per cent                    | gal. | —    | (Fixed Price) | 1 50  |
| Toluol, in tank cars                   | gal. | —    | (Fixed Price) | 1 55  |
| Toluol, for non-military use, in drums | gal. | 45   | —             | 55    |
| Xylol, pure, water white               | gal. | 18   | —             | 28    |
| Solvent naphtha, water white           | gal. | 12   | —             | 15    |
| Solvent naphtha, crude, heavy          | gal. | 39   | —             | 40    |
| Cresote oil, 25 per cent               | gal. | 30   | —             | 32    |
| Dip oil, 20 per cent                   | ton  | 8 00 | —             | 20 00 |
| Pitch, various grades                  | lb.  | 1 05 | —             | 10    |
| Carbolic acid, crude, 95-97 per cent   | lb.  | 1 60 | —             | 65    |
| Carbolic acid, crude, 90 per cent      | lb.  | 35   | —             | 38    |
| Carbolic acid, crude, 25 per cent      | lb.  | 18   | —             | 20    |
| Cresol, U. S. P.                       | lb.  | —    | —             | —     |

### Intermediates, Etc.

|                                 |     |       |         |       |
|---------------------------------|-----|-------|---------|-------|
| Alpha naphthol, crude           | lb. | 1 00  | —       | 1 10  |
| Alpha naphthol, distilled       | lb. | 1 60  | —       | 1 70  |
| Alpha naphthylamine             | lb. | 60    | —       | 65    |
| Aniline oil, drums extra        | lb. | 27    | —       | 28    |
| Aniline salts                   | lb. | 34    | —       | 36    |
| Anthracene, 80 per cent         | lb. | 3 65  | Nominal | —     |
| Benzaldehyde (f. c.)            | lb. | 1 75  | —       | 2 00  |
| Benzidine, base                 | lb. | 1 40  | —       | 1 50  |
| Benzidine, sulphate             | lb. | 3 40  | —       | 3 60  |
| Benzic acid, U. S. P.           | lb. | 3 00  | —       | 3 25  |
| Benzozate of soda, U. S. P.     | lb. | 2 30  | —       | 2 50  |
| Benzyl chloride                 | lb. | 10 00 | —       | 12 00 |
| Beta naphthol, nzoate           | lb. | 85    | —       | 90    |
| Beta naphthol, sublimed         | lb. | 2 65  | —       | 2 80  |
| Beta naphthylamine, sublimed    | lb. | 15    | —       | 20    |
| Dichlor benzol                  | lb. | 4 50  | —       | 5 00  |
| Diethylaniline                  | lb. | 36    | —       | 38    |
| Dinitro benzol                  | lb. | 40    | —       | 42    |
| Dinitrochlorobenzol             | lb. | 60    | —       | 70    |
| Dinitronaphthalene              | lb. | 65    | —       | 75    |
| Dinitrotoluol                   | lb. | 46    | —       | 50    |
| Dinitrophenol                   | lb. | 75    | —       | 80    |
| Dimethylaniline                 | lb. | 75    | —       | 80    |
| Diphenylamine                   | lb. | 2 60  | —       | 3 00  |
| Hydroquinone                    | lb. | 1 75  | —       | 2 00  |
| Metanaphthylendiamine           | lb. | 17    | —       | 20    |
| Monochlorobenzol                | lb. | 083   | —       | 093   |
| Naphthalene, flake              | lb. | 10    | —       | 103   |
| Naphthalene, balls              | lb. | 1 20  | —       | 1 30  |
| Naphthalene, acid, crude        | lb. | 1 00  | —       | 1 10  |
| Naphthylamine-di sulphonic acid | lb. | 45    | —       | 50    |
| Nitro naphthalene               | lb. | 60    | —       | 65    |
| Nitro toluol                    | lb. | 15    | —       | 18    |
| Ortho-amidophenol               | lb. | 1 00  | —       | 1 25  |
| Ortho-dichlorobenzol            | lb. | 7     | —       | 100   |
| Ortho-toluidine                 | lb. | 4 00  | —       | 4 50  |
| Ortho-nitro-tolol               | lb. | 4 00  | —       | 5 00  |
| Para-amidophenol, base          | lb. | 15    | —       | 20    |
| Para-amidobenzol, H. Cl.        | lb. | 1 60  | —       | 1 85  |
| Para-dichlorobenzol             | lb. | 1 50  | —       | 1 60  |
| Paranitraniline                 | lb. | 3 75  | —       | 4 00  |
| Para-nitro-tolol                | lb. | 2 00  | —       | 2 25  |
| Paraphenylendiamine (base)      | lb. | 3 50  | —       | 4 00  |
| Para-toluidine                  | lb. | 3 4   | —       | 40    |
| Phthalic anhydride              | lb. | 5 00  | —       | 7 00  |
| Phenol, U. S. P.                | lb. | 8 00  | —       | 9 00  |
| Resorcin, technical             | lb. | 1 10  | —       | 1 20  |
| Resorcin, pure                  | lb. | 1 50  | —       | 2 00  |
| S. lievin's acid                | lb. | 30    | —       | 32    |
| Sulphanilic acid, crude         | lb. | 2 50  | —       | —     |
| Tolidin                         | lb. | 85    | —       | 90    |
| Toluidine-mixture               | lb. | —     | —       | —     |

## Financial, Construction and Manufacturers' News

### Construction and Operation

#### Arkansas

**FORT SMITH.**—The Arkansas Mining & Mercantile Co., Boone and Marion Counties, will build a 200-ton concentration plant requiring drills, sludge and slime tables, engines, pits, boilers, compressors, ore crushers, track cars, belts and mill hardware. Estimated cost, \$60,000. F. A. Handlen, superintendent.

#### Connecticut

**COSCOB.**—The Mianus Manufacturing Co., 615 Fourth Ave., New York City, will build a 4-story, 42 x 145 ft. reinforced concrete dyehouse here. Estimated cost, \$40,000. Lockwood Greene Co., 101 Park Ave., New York City, engineers.

**NEW BRITAIN.**—The Traut & Hine Manufacturing Co., 510 Stanley St., has awarded the contract for the construction of a 1 and 3-story, 43 x 83 and 44 x 70 ft. concrete and brick addition to its factory for the manufacture of metal novelties, to W. H. Allen, New Britain. Estimated cost, \$35,000.

**TORRINGTON.**—The Fitzgerald Manufacturing Co. will build a 2-story, 50 x 300 ft. concrete and brick factory for the manufacture of brass goods on Railroad Ave. Estimated cost, \$60,000. E. H. Waterbury, Torrington, architect.

#### Georgia

**BRUNSWICK.**—The Ordnance Division, War Department, Washington, D. C., has awarded the contract for the construction of a picnic acid plant, here, to Butterworth-Judson Co., 51 Broadway, New York City. Estimated cost, \$7,000,000.

#### Indiana

**KOKOMO.**—The Kokomo Steel & Wire Co. will build a 1-story, 100 x 800 ft. reinforced concrete and brick factory. Estimated cost, \$150,000.

#### Kansas

**BAXTER SPRINGS.**—The Great Western Mining Co. will build a 500-ton concentration plant requiring lumber, engine, boilers, sludge tables, belts, crushers, hardware and scales. Estimated cost, \$75,000. O. F. Renner, superintendent.

**BAXTER SPRINGS.**—C. M. Mitchell will build a 200-ton concentration plant at his mine here and install mill hardware, lumber, sludge and slime tables, engine, boiler, crusher, air compressor and belts. Estimated cost, \$45,000. Buck Shelton, Baxter Springs, superintendent.

**BAXTER SPRINGS.**—C. E. Phillips will build a 150-ton concentration plant. Estimated cost, \$60,000. The company is in the market for sludge and slime tables, mill hardware, ore cars, lumber, drills, engines, boilers, belts. John Phillips, superintendent.

**GALENA.**—O. C. Hamilton, Connor Hotel, Joplin, Mo., will build a 200-ton concentration plant at his mine here and is in the market for ore crushers, ore cars, lumber, mill hardware, sludge and slime tables, air compressors, pipes and belts. Estimated cost, \$65,000.

**GALENA.**—The Lucky Jim Mining Co. will build a 200-ton concentration plant and install machinery, including sludge and slime tables, crushers, lumber mill hardware, scales, belts, air compressors and drills. Estimated cost, \$25,000. O. C. Hamilton, Galena, superintendent.

**GALENA.**—The Stag Mining Co. will build a 200-ton concentration plant and install machinery, including sludge and slime tables, ore crushers, lumber, drills and compressors. Estimated cost, \$60,000. F. L. Cook, superintendent.

**GALENA.**—The Stag Mining Co. will remodel its 150-ton mill to a 250-ton mill. Estimated cost, \$25,000. The company is in the market for lumber, mill hardware, belts, crushers, air compressors, ore bins, cars, track and drill. R. S. Harris, superintendent.

**TRECE.**—The Phoenix Lead & Zinc Co., Phoenix, will remodel its 200-ton mill and install belts, rollers, track, hardware and ore cars. Estimated cost, \$25,000.

#### Kentucky

**LOCKLAND.**—J. B. Speed & Co., Speed Building, Louisville, will build a potash plant. Estimated cost, \$100,000.

**LOUISVILLE.**—The Magic Keller Soap Works, 2745 Stecker St., has awarded the contract for the construction of a factory to the National Concrete Construction Co., engineers, Board of Trade Building.

#### Louisiana

**ALEXANDRIA.**—The Wm. Polk Co., 1209 Third St., will build a plant for manufacturing soap stocks, etc. Wm. Polk, care company, interested.

#### Maryland

**BALTIMORE.**—The American Can Co., Maryland Trust Building, will build a 4-story, 36 x 105 x 176 ft. reinforced concrete brick and steel factory on Boston and Hudson Sts., Canton. Estimated cost, \$180,000. N. M. Loney, 120 Broadway, New York City, architect.

**BALTIMORE.**—The Baltimore Tube Co., Wicomico and Ostend Sts., has purchased a site at Wicomico and Bayard Sts., and will build an addition to its plant here.

**BALTIMORE.**—Bartlett-Hayward Co., Scott and McHenry Sts., has awarded the contract for the construction of a 1-story, 479.5 x 618 ft. frame munition factory to Morrow Bros., Fidelity Building. Estimated cost, \$19,000.

**BALTIMORE.**—The Bureau of Yards & Docks, Navy Department, Washington, D. C., will build additional buildings at Marine Hospital, Remington Ave. and 31st St., including laboratories. Dr. C. W. Vogel, in charge.

**BALTIMORE.**—Elliott Machine Corporation, Bush and Severn Sts., will build a 1-story, 50 x 205 ft. reinforced concrete tool machine shop at Bayard and Wicomico Sts. Estimated cost, \$75,000.

**INDIAN HEAD.**—Bureau of Yards & Docks, Navy Department, Washington, D. C., will build 11 buildings as an extension to its powder factory. Estimated cost, \$338,500.

#### Michigan

**BATTLE CREEK.**—The Rich Steel Products Co. has awarded the contract for the construction of a 1-story, 49 x 112 ft. warehouse and a 49 x 256 ft. shop, mill construction, to C. Rasmussen, 254 West Randolph St., Chicago, Illinois.

#### Missouri

**DUENWIG.**—Frank Starkweather will remodel the 150-ton concentration plant recently destroyed by fire. Estimated cost, \$45,000. The company is in the market for sludge and slime tables, lumber, mill hardware, drills, rollers, engines, track and ore cars. P. Starkweather, superintendent.

**DUENWIG.**—The Vacation Mining Co. will build a 200-ton concentration plant. Estimated cost, \$65,000. The company is in the market for sludge and slime tables, mill hardware, ore cars, track engine, boilers, air compressors, belts, drills and crushers. Bud Craig, Joplin, superintendent.

**KANSAS CITY.**—C. R. Cook, Palm Co., 2107 Broadway, will rebuild its plant recently destroyed by fire entailing a loss of \$40,000.

**ORONOGO.**—The Connecticut Zinc Corporation, Joplin, will build an 1800-ton concentration plant here and install machinery, including sludge and slime tables, air compressors, belts, ore cars, crushers, scales, drills, engines. Estimated cost, \$200,000. Sidney Wilkens, Independent Bldg., Joplin, superintendent.

**WACO.**—The George Ball Mining Co. will build a 150-ton concentration plant. Estimated cost, \$60,000. The company is in the market for sludge and slime tables, crushers, jigs, mill hardware, belts, mill rollers, air compressors and conveyors. G. Ball, Webb City, superintendent.

#### New Jersey

**JERSEY CITY.**—The Air-Reduction Co., 177 Pacific Ave., has awarded the contract for the construction of a 4-story, 40 x 110 ft. reinforced concrete addition to its plant, to James Mitchell, 76 Montgomery St. Estimated cost, \$40,000.

**NEWARK.**—The Essex Foundry Co., Murray St., will build a 1-story, 75 x 180 ft. brick and steel factory on Elm St. Estimated cost, \$25,000.

#### New York

**BROOKLYN.**—The Kollmorgen Optical Co., 35 Steuben St., has awarded the contract for the construction of a 19 x 38 ft. concrete addition to its factory at Steuben St. north of Park Ave., to Metropolitan Corning & Sheet Metal Works, Flushing, and Metropolitan Aves. Estimated cost, \$5,000.

**BROOKLYN.**—The Improved Appliances Co., 455 Kent Ave., has awarded the contract for the construction of a 4-story, 60 x 92 ft. reinforced concrete and brick addition to its factory to Rufus H. Brown, 350 Fulton St. Estimated cost, \$15,000. Noted June 15.

**NIAGARA FALLS.**—The United States Light & Heat Corporation has awarded the contract for the construction of a 19 story, 150 x 300 ft. factory for the manufacture of lighting equipment and storage batteries, to Lauer & Mack, 1834 Pierce Ave. Estimated cost, \$35,000.

**PEARL RIVER.**—The Lederle Antitoxin Laboratory has awarded the contract for the construction of 2-story, 36 x 54 ft. brick veterinary laboratory to Ferber Construction Co., 16 Union Co. Rd., Hackensack, N. J. Estimated cost, \$25,000.

**SYRACUSE.**—The Brown-Lipe-Chapins Co., 110 Seneca St., will build a 2-story, 60 x 120 ft. concrete and brick factory for the manufacture of electrical fittings. Estimated cost, \$20,000. Taylor & Bouta, Gurvey Building, architects.

**SYRACUSE (Split Rock).**—The Sement-Solvay Co., River Road and Tonawanda St., Rochester, will rebuild its plant consisting of three T. N. T. plants, one nitric acid plant, one office building, one laboratory and one boiler house, at Milton Ave., Split Rock, which was recently destroyed by fire.

#### Ohio

**AKRON.**—City plans to build a modified Imhoff sewage disposal plant for Summit County Inland and Adams Sts. Estimated cost, \$18,000. M. P. Lauer, 707 Peoples Saving and Trust Building, engineer.

**CINCINNATI.**—The Lodge & Shipley Machine Co., 3055 Colerain Ave., will build a 1-story, 90 x 540 ft. brick and steel building for the manufacture of lathes. Estimated cost, \$100,000. Zettl & Rapp, Johnston Building, architects.

**CINCINNATI.**—John H. McGowan Co., 52 Central Ave., will build a 2-story, 87 x 87 ft. concrete and brick factory for the manufacture of pumping and hydraulic machinery. Thielt & Lee, Fourth National Bank, architects.

**CLEVELAND.**—The International Steel Tie Co., 16702 Waterloo Rd., will build a 1-story, 50 x 220 ft. steel factory. Estimated cost, \$30,000.

**CLEVELAND.**—The New York Central Railway, St. Clair and West 3d Sts., will build a 1-story, 97 x 163 ft. reinforced concrete, brick and steel locomotive repair shop at 564 East 152d St. Estimated cost, \$150,000.

**CLEVELAND.**—K. V. Painter, 3240 Fairmount Blvd., has awarded the contract for the construction of a 2-story, 108 x 132 ft. reinforced concrete and mill construction factory and salesroom for the manufacture of automobiles, to A. J. Kilbourne Co., 505 Sweetland Building. Estimated cost, \$50,000.

**CLEVELAND.**—The Steel Products Co., 2196 Clarkwood Ave., has awarded the contract for the construction of a 1-story, 9 x 100 ft. concrete and brick addition to its factory at East 65th St., to S. W. Emerson, 1900 Euclid Building. Estimated cost, \$14,000.

**CLEVELAND.**—The Western Machine Products Co., 7209 St. Clair St., has awarded the contract for the construction of a 2-story, 105 x 122 x 126 ft. concrete, brick and steel addition to its machine shop to Christian-Schwarzenberg & Gaede Co., 900 Euclid Building. Estimated cost, \$25,000.

**EUCLID.**—The Bishop-Babcock-Bocker Co., 1803 East 40th St., will build a group of factory buildings on a 26-acre site on Bliss Road for the manufacture of tacks, nails and bras.

**MARIETTA.**—The United States Government will build machine shops here for repairing Ohio River dams in Wheeling District. Address Col. H. W. Stickie, Wheeling, West Virginia.

**SPRINGFIELD.**—The Eagle Engineering Co., West Main St. and Bell Ave., will build a 1-story, 50 x 160 ft. reinforced concrete, brick and steel factory. Estimated cost, \$15,000.

**STRUTHERS.**—The Struther Furnace Co. has awarded the contract for the construction of a river intake plant to Baker, Dunbar & Allen, Union Ave., Pittsburgh, Pa. Estimated cost, \$102,000.

## Oklahoma

**BARTLESVILLE.**—The United States Government, Bureau of Mines, will build a 1-story, 40 x 100 ft. laboratory here.

**COMMERCE.**—The Safeguard Mining Co. will build a 200-ton concentration plant requiring lumber, mill hardware, boilers, engine, crushers, sludge and slime tables. Estimated cost, \$70,000.

**DOUZHAT.**—The Maurice Mining Co. will build a 300-ton concentration plant. Estimated cost, \$75,000. The company is in the market for a derrick, sludge and slime tables, lumber, mill hardware, crushers, boilers, engine, conveyors and compressors.

**GRANDY.**—The Grandy Consolidated Mines Co., Miami, will build a 300-ton concentration plant and install sludge tables, motors, mill lumber, mill hardware, air compressors, ore track bins, slime tables, boilers and engines. Estimated cost, \$13,000. W. G. Wilkerson, superintendent.

**LINCOLNVILLE.**—The Miami Sunrise Mining Co., Miami, will build a 200-ton concentration plant at its mine near here, requiring sludge tables, engines, boilers, drills, lumber, mill hardware and air compressors. Estimated cost, \$60,000.

**LINCOLNVILLE.**—The Nemo Mining Co. will remodel its 200-ton concentration plant and install machinery, including sludge tables, belts, crushers and drills. Estimated cost, \$10,000.

**MIAMI.**—The Picher-Oklahoma Mining Co. will build an 800-ton concentration plant requiring sludge and slime tables, mill hardware, crushers, air compressors, belts and ore cars. Estimated cost, \$75,000. A. J. Harrington, superintendent.

**MIAMI.**—The United Development Co., Oklahoma City, will build a 250-ton concentration plant and install machinery, including mill hardware, lumber, roofing, engine, boilers, crushers, belts and air compressors. Estimated cost, \$75,000. V. E. Conkle, superintendent.

**OKLAHOMA CITY.**—The Indian Chief Mining Co. will build a 300-ton concentration plant. B. C. Clark, Purcell, president.

**PEORIA.**—The Dallas Miami Mining Co. will build a 250-ton concentration plant. Estimated cost, \$65,000. The company is in the market for mill hardware, crushers, motors, belts, track, ore cars, mill hardware, crushers, rollers, engine and compressors. A. J. Herrington, superintendent.

**PEORIA.**—The King Bee Mining Co. will build a 200-ton concentration plant and install machinery, including sludge and slime tables, drills, compressors, belts, mill hardware, ore cars and lumber. Estimated cost, \$60,000.

**PEORIA.**—The L. C. H. Corporation has awarded the contract for the construction of a 200-ton concentration plant to Hess Construction Co., 1831 Moffet Ave., Joplin, Mo. Estimated cost, \$45,000. The company is in the market for mill hardware, crushers, mill hardware, lumber, crushers, engine, boilers, belts and air compressors.

**PICHER.**—The Ottawa Metals Co. will build a 175-ton concentration plant requiring mill hardware, lumber, engine, rollers, slugs, rollers, crushers, air compressors, belts, ore cars and conveyors. Estimated cost, \$45,000.

**PICHER.**—The Picher Lead Co. will build a 200-ton concentration plant. Estimated cost, \$60,000. The company will install sludge and slime tables, mill lumber and hardware, ore cars, track, belts, engine, boilers, rollers, air compressors and pipes. C. Potter, superintendent.

**QUAPAW.**—The Quapaw Jack Lead & Zinc Co. will build a 200-ton concentration plant and install machinery, including drills, air compressors, sludge and slime tables, mill hardware, crushers, rollers, conveyors. Estimated cost, \$65,000. B. W. Ward, superintendent.

**QUAPAW.**—The Quapaw Mining Co. will build a 250-ton concentration plant requiring mill hardware, sludge and slime tables, drills, belts, rope and air compressors. Estimated cost, \$72,000.

**QUAPAW.**—The Ruth Strike Mining Co. will build a 300-ton concentration plant and install machinery, including crusher, sizer, compressor, gas engine, sludge and slime tables, lumber, mill hardware, belts, track and ore car. Estimated cost, \$30,000. A. O. Baker, Shawnee, superintendent.

**SPAVINAW.**—The Red Granite Copper and Water Power Co., Strand, will build a concentration plant. Estimated cost, \$25,000. The company is in the market for crushers, engine, rollers, ore cars, bins, lumber, track screens, belts and mill hardware. W. E. Hudson, Connor Hotel, Joplin, Mo., superintendent.

**ST. LOUIS.**—The Miami Wonder Mining Co., Miami, will build a 200-ton concentration plant at its mine near St. Louis and install crushers, mill machinery, sludge and slime tables, belts, engine, rollers, drills, boilers, air compressors. Estimated cost, \$60,000. A. V. Ellis, superintendent.

## Pennsylvania

**PHILADELPHIA.**—The Niles-Bement-Pond Co., 21st and Callowhill Sts., has awarded the contract for the construction of a 1-story, 65 x 115 ft. addition to its foundry on Ruffner and Donath Sts., to Austin Co., Bulletin Bldg. Estimated cost, \$20,000.

**READING.**—The Philadelphia & Reading Railway has awarded the contract for the construction of a 1-story, 100 x 150 ft. brick and steel machine shop to E. Warfel, Lancaster. Estimated cost, \$40,000.

## Rhode Island

**PAWTUCKET.**—The Potter & Johnston Co., Newport Ave., has awarded the contract for the construction of a 1-story, 171 x 486 ft. mill construction plant for the manufacture of shells and glass. The Industrial Trust Bldg., Providence. Estimated cost, \$150,000.

## Texas

**BROWNWOOD.**—The Brownwood Glass Manufacturing Co. will build a glass factory. Estimated cost, \$100,000. H. Wagner, Tulsa, Okla., president.

**CISCO.**—The Liberty Refining Co., C. A. Gray Building, will build an oil refinery here. G. J. Ames, president.

## Washington

**SEATTLE.**—The Alaskan-Copper Works, 1041 Railroad Ave., will build a 1-story, 50 x 87 ft. machine shop at 3600 East Marginal Way. Estimated cost, \$6,000. Frank Cruise, Washington Block, architect.

**SEATTLE.**—The Seattle Pipe & Galvanizing Co., 1st Ave. South and Stacy St., has awarded the contract for the construction of a 1-story, 52 x 150 ft. plant for galvanizing ship supplies and heavy hardware to Geo. Eckman, Pacific Block. Estimated cost, \$40,000.

**SEATTLE.**—P. J. Appleton, 1111 1st Ave., has awarded the contract for the construction of a 2-story, 43 x 200 ft. foundry machine shop at 1410 Dearborn St. to W. Husekamp, 1255 John St. Estimated cost, \$5,000.

## Quebec

**TEMISKAMING.**—The Kipawa Fibre Co., in which the Klondan Pulp & Paper Co., 355 Beaver Hall St., Montreal, is interested, will build a pulp and paper plant.

## Wisconsin

**MILWAUKEE.**—The Standard Steel Corporation, Hopkins Rd. and Lake St., will build a 2-story, 40 x 200 ft. factory and a 40 x 140 ft. foundry. F. D. Chase, 122 St. Michigan Ave., Chicago, Ill., architect. E. J. De Guenther, 908 Majestic Building, interested.

**THE SCIENTIFIC UTILITIES CO., INC.,** 84 East 11th Street, New York City, has recently been incorporated by the trustees of the company with the American Scientific Instrument Co. The new company is a modern glass blowing shop and is prepared to furnish the trade with special apparatus.

**THE TRAYLOR ENGINEERING AND MANUFACTURING CO. of Allentown, Pa.,** announce the following election of officers: Mr. Samuel W. Traylor, chairman of the board, Mr. William J. Roberts, president and Mr. H. Battersby, vice-president and treasurer.

**THE MULTI METAL CO., INC.,** is the new name for the Multi Metal Separating Screen Co., which took effect July 1, 1918.

**THE ABRONOME COMPANY OF PITTSBURGH,** (formerly the American Portland Cement Metal Company) announces the removal of its

Chicago office on July 1, 1918, to the Railway Exchange Building, New York. Mr. T. O'Neill will continue in charge as district manager.

**THE INDUSTRIAL ELECTRIC FURNACE COMPANY, Chicago,** makers of the Snyder Electric Furnace, are installing a three-ton furnace in the new building of the Atlantic Foundry Company, Akron, Ohio. It is a three-phase furnace built for acid operation on general steel casting work, and was purchased as a by-product of scientific research. The company has a general manager, president and general manager, and John Steckel, treasurer and purchasing agent, of the Atlantic Foundry Co.

**THE PYROLYTIC INSTRUMENT CO.,** 636 East State Street, Trenton, N. J., announce that their Northrup-Ajax high-frequency induction furnace developed by Dr. E. F. Northrup for the Ajax Metal Company of Philadelphia is now available for scientific and experimental purposes in five sizes—6 kw., 8 kw., 12 kw., 16 kw. and 20 kw. This furnace operates upon a radically new principle and is said to give results not obtainable by any other type of electric furnace heretofore invented. It is fully described in a new twenty page illustrated circular just issued by the Pyrolytic Company. To those interested in acquiring one of these furnaces this circular will be sent upon request.

**PITTSBURGH TESTING LABORATORY** announces the removal, July 1st, 1918, from its temporary quarters in the E. T. O'Neill Law Building to its new office and laboratory buildings at 612-620 Grant Street, Pittsburgh, Pa. Our laboratories will be larger and better equipped than those in our old quarters, the P. T. L. Building, at Seventh and Bedford Avenues, which we turned over to the Government on April 1st, 1918.

**THE KOPPERS COMPANY, Pittsburgh, Pa.,** has been awarded a contract by the Jones and Laughlin Steel Company for the construction of a by-product coke plant of 300 ovens, which will have a washing capacity of approximately 2,000,000 tons per year, which will replace beehive coking capacity of that amount. This plant will be equipped for recovering ammonia in the form of ammonium sulphate of tar and of benzol and toluol as pure products. The ammonium sulphate and pure toluol will be sold to the Government for war purposes. The steel company plans to use the gas in its steel plant operations.

A NEW 6-TON ACID OPEN-HEARTH FURNACE has recently been completed by the Atlantic Steel Castings Co., Chester, Pa., and is being installed at the light casting of nickel steel. The company is engaged on Government war work.

**THE ZENITH FURNACE CO., Duluth, Minn.,** have retained Freyn, Brassett & Co., Peoria, Ill., Chicago, for the remodeling of their furnace, the installation of a Brassett gas-washing and drying unit, the erection of a new hot-blast stove and other plant improvements.

**FOUR NEW GAS PRODUCERS,** built by the Morgan Construction Co., Worcester, Mass., are being installed at the Youngstown Sheet & Tube Company's plant at Youngstown, Ohio, to replace the old producers.

**THE HANCOCK ROCK IRON CO.,** Hanging Rock, Ohio, have awarded a contract to the A. G. McKee Co., Cleveland, for improvements to the Hamilton plant which will include a skip bridge, conveying distributor, scale cars and a one 50-ton transfer car.

**THE CANADIAN FERRO ALLOYS, LTD.,** Shawinigan Falls, Que., Canada, is building a plant for the production of ferro alloys. They expect to ship in addition to their regular products, 17 tons of 50 per cent ferrosilicon daily.

## Manufacturers' Catalogs

**THE CUTLER-HAMMER MANUFACTURING CO., Milwaukee, Wisconsin:** A pamphlet on battery charging equipment for trucks and vehicles and industrial trucks. Another pamphlet is issued by the above company on C-H 9116 starting switch for squirrel cage motors.

**THE CLARAGE FAN COMPANY, Kalamazoo, Mich.:** Catalog No. 22 on style "C" pressure blowers giving a general description, general data and capacity tables.

**THE P. H. & F. M. ROOTS COMPANY, Connersville, Ind.:** Catalog 63 on the Roots Rotary Gas Exhaustors, for promoting feature is the publication of tables of engineering data, designed to make the catalog valuable as a reference book to any one interested in the manufacture or use of gas. This catalog describes and illustrates rotary gas exhaustors for foul gas pumping service, corrosive gas handling with high-pressure booster service and special linings.

## September's Conventions

THE month of September promises to be a busy one for those who have occasion to attend professional gatherings. The American Institute of Mining Engineers holds its one hundred and seventeenth meeting in Colorado through the first week of the month, visiting Denver, Colorado Springs, Cripple Creek and Pueblo. The American Chemical Society will convene in Cleveland, Ohio, the following week, holding meetings on the tenth to the thirteenth inclusive. Apparently no meetings have been scheduled for the third week in the month but in the following week the Fourth National Exposition of Chemical Industries will be held at Grand Central Palace, New York. The American Electrochemical Society closes the fall schedule with meetings at Princeton, N. J., from Sept. 30 to Oct. 2.

This is a rather rapid-fire program for those whose interests in chemistry and metallurgy make attendance on the conventions of these societies desirable if not essential. In spite of the earlier agitation against wartime conventions there seems to be no abatement of interest, which may be attributed to the fact that not only are the conventions profitable in themselves, but they afford a very desirable form of relief from the strenuous personal schedules which most technical men are obliged to lay out for themselves.

It has been our own observation that very definite and tangible results of benefit to the war program of the country come from these professional gatherings. There is much information of a technical nature which can not be offered for publication, but which men will communicate to each other freely if the opportunity of a personal meeting is afforded. The convention supplies the common meeting ground with the right atmosphere for professional intercourse. It will be our pleasant duty to report all these gatherings fully for the benefit of those who cannot attend.

## Platinum, Rice and War Weddings

WE NEED an enlightened public conscience on the subject of platinum. We have one on the subject of food and it worked wonders in enabling us to conserve our supplies, feed ourselves and our Allies, and in general get the matter so well in hand that the Food Administrator could announce recently that there is no danger of a crisis. If the general public had as keen a sense of patriotism regarding platinum as it has on the subject of food, we would hear less of a platinum shortage and our supply of the metal would be plainly useful instead of doubtfully ornamental.

What the lack of appreciation of the platinum situation means among good citizens of a high degree of

intelligence is well illustrated by a recent war wedding to which we were a witness. The groom was an army officer, shortly to sail overseas in the performance of his patriotic duty, there to make the supreme sacrifice if necessary, and placing reliance for his safety and support on the steady production of munitions at home. The bride was a fair daughter of a family of the better class, but more familiar with platinum as an ornament than a catalyst. Because platinum has been in vogue for wedding and engagement rings, and wishing to present his bride with the best the market afforded, the groom had selected jewelry of the white metal, wholly unmindful of the anomaly of a soldier sacrificing in ornamentation that which is an essential to the production of the munitions on which he must rely for his personal safety. And after the ceremony was over and the couple left the scene, the assembled company patriotically refrained from spoiling fifteen cents worth of rice wherewith to perpetuate an age-old tradition on such occasions. All of which suggests the need of a conscience on platinum as first mentioned. Is it not time that chemists and metallurgists spread the gospel of platinum for munitions and publicly frown upon slacker uses of platinum? The people are intelligent and patriotic at heart, but uninformed and therefore careless in their actions. It is wholly a question of education, for which technologists are to be held responsible.

#### Test Iron Ores and Fluxes for Potash

DOMESTIC production of potash in 1917, according to the U. S. Geological Survey, amounted to 32,366 tons of available  $K_2O$ . Natural brines yielded 20,652 tons and easily proved to be the premier source. Kelp was second with 3572 tons; and molasses, alunite and cement-kiln dust followed with 2846, 2402 and 1621 tons respectively. Thereafter no item in the list attains the dignity of a production requiring more than three figures, and blast-furnace dust ends the list with a production of but 185 tons  $K_2O$ , being appreciably less important than wood ashes, the residue from evaporation of Steffens water from sugar refineries or similar residues from wool washing and other industrial wastes.

Judged from these figures alone, blast-furnace dust would not appear to be much of a factor in the prospective production of potash in this country. And yet there are certain technical and economic features about the recovery of potash from this source that lead us to urge chemists and metallurgists everywhere to be diligent in analyzing all iron ores and fluxes for this important mineral.

Our future independence in potash supply is likely to rest largely in that item of our production which is most nearly a cheap by-product. Careful and continued geological exploration for several years has afforded no hope of discovering deposits comparable to those of Europe, or indeed any that seem important. By-products, therefore, assume added value and it behooves us to take careful stock of this asset. The by-product which will be most valuable will be one that accompanies a material for which there is an unlimited demand, so that no glut of the principal market can reduce the output of the minor product.

Iron ores and fluxes fulfill in a peculiar degree all the

conditions for an almost ideal source of potash as a by-product, and make a careful survey desirable if not imperative. These materials are used in large quantities, so that if they contain what would otherwise be a negligible percentage of potash they will nevertheless yield an appreciable total in the aggregate. The potash content can be recovered in the process of cleaning the furnace gases, which is in itself a desirable operation even if no valuable by-product were sought. It is quite evident, then, that if our large iron deposits should be found to be potash-bearing, we have a source of potash that is practically without expense. Transportation and treatment charges would be absorbed by the principal product, and the by-product would be clean profit. On such a basis it would not be difficult to compete with German potash at any price. We deem the subject worthy of the most careful investigation and shall be glad to open our columns to those who may undertake researches in this line or who may have knowledge of the extent to which potash exists in our iron ores, dolomite limestones and coke.

#### Science and the German Language

THERE is a great deal of hysteria in the daily press about dropping the study of the German language from schools and even colleges. We see no good in the plan. It reminds us of the man who bit off his nose to spite his face. Why interject non-essentials at a time like this? Of course we do not favor schools conducted in the German language, and we believe in making short shrift of German propaganda either now or at any other time—until the German people get over their present delirium and know enough to be ashamed of themselves.

Let us try to get a broad view of the situation. The Germans followed Kant in the belief that there is no relation between science and ethics. The Prussian drill in obedience to authority had its effects here as well as elsewhere and Kant, being a philosophical authority, became the final and binding word upon the German conscience. For generations the German people have been almost feeble-minded in their inhibitions against the voice of authority. "There can be no revolution in Germany," said Heine, "because revolution is *verboten*." But now the Germans have very effectively done as they were told; they have divorced science from ethics and—we see the results.

In times past, however, they had their periods of enlightenment, and in elucidation of this we shall repeat an example that we have mentioned before. It was sometime in the seventies that Professor Josiah Willard Gibbs of Yale University read a paper on the phase rule, before the Connecticut Academy of Sciences at New Haven. It is not of record that anybody understood what he was talking about. Then many years later, sometime in the nineties as we recall it, the elder Ostwald, being still in his right mind, set out to find all that he could about Willard Gibbs, whose infrequent contributions had aroused his lively interest. Looking over the published transactions of the Connecticut Academy, he discovered to his unutterable delight the very thing he had long been wishing for: the phase rule stated and worked out. He immediately trans-

lated it into German, giving full credit to the author and his source of information, and published it to the great illumination of the scientific world. It is fair to say that we Americans got the phrase rule from the German, although it appeared originally within less than 100 miles from New York, and it was written and delivered in English.

If we didn't know enough then to see a good thing when it was put before us, it stands to reason that we are capable of letting other good things slip by unobserved, even in this day of blind rage. And it is a bad thing for science in America or anywhere else to let additions to enlightenment pass by, whether they come from Germany or Zambesi or Timbuktu. Facts are facts and information is information. We must not misuse them, neither must we close our eyes to them. The German language is to-day the richest in chemical literature as it is also in certain other branches of science, and to prevent the study of it would be nothing more than giving way to hysterics. It would often involve waiting a year for partial and inadequate translations. The war is not won yet; everyone of us has a man's job ahead of him, and there is neither profit nor wisdom in browsing about in the silly-ass pasture.

### Flexibility of the Steel Industry

THE combination in the steel industry of all steel-making departments being operated as fully as possible with many finishing departments operating at only about 60 per cent of their capacity is one that would not have been believed possible a few years ago. Normally the sum total of the finishing capacity exceeds but slightly the total ingot-making capacity, and when there is full production of ingots there must necessarily be nearly full employment of finishing departments. For a time after the European war started, moreover, there was erection of open-hearth furnaces without attendant increases in finishing capacity, thus making the alignment between steel-making and steel-finishing capacity closer than ever.

Yet the condition to-day is that every works is striving to turn out a maximum tonnage of ingots while the rod, merchant and sheet mills are operating at only about 60 per cent of capacity, the production of steel pipe is light and the production of rails far below capacity. Ingots, blooms and billets are extremely scarce. The finished products that are most needed for war purposes are being produced in great volume while the products less needed for war purposes are being produced in small volume.

The steel industry is showing a flexibility that would not have been expected. Indeed, there were many predictions a year and more ago that our entrance into the war could not make steel of all descriptions scarce, for the war would require large tonnages of some finished forms and little tonnage of others, which perforce would be plentiful. Thus the steel industry has adapted itself in remarkable manner to the peculiar demands made upon it.

Several causes have contributed to make this alignment possible. The two chief factors are the heavy production of shell steel and the large increase in plate-

rolling capacity. Precise figures are not available, but a fair estimate is that half a million net tons of shell steel a month is being made. The records at Washington are made up in net tons, so that unit may as well be used. This shell steel involves the use of scarcely any finishing capacity. Next, there is an output of plates probably materially in excess of half a million tons a month, an increase of considerably more than 50 per cent over the output in 1916, when every effort was being made to swell the production of plates, which were easily the scarcest commodity in the steel market. The major portion of the new plate mill construction has been without increase of capacity of the attendant steel works and indeed some plate mills have been built without slabbing mill capacity, requiring slab ingots or blooming mill slabs.

A relatively minor factor from a tonnage standpoint, and yet an important one, is the heavy operation of the tin-plate mills. They have lately been producing at the rate of 160,000 net tons a month, against an output of 115,000 tons a month in 1916. This heavy operation tends to make crude steel scarce in general, and in particular it makes such a drain upon the sheet-bar supply that the sheet mills are but poorly provided. The proportion of the total steel supply passing into sheet bars is not much under normal, but the division of the sheet-bar supply is quite abnormal.

The structural mills are not operating at an abnormally heavy rate but are probably consuming their usual proportion of the total steel supply, and this leaves it that the operations of rod bar, rail, sheet, merchant and skelp mills are very far below capacity, probably averaging in the neighborhood of 60 per cent. It is understood that the rod mills are definitely limited to a 60 per cent operation.

The production of ingots in June was at the rate of about 43,500,000 gross tons a year, there having been an increase in the rate each month since the very low rate of last January. For a period of years before the war the output of finished rolled steel was almost precisely, year by year, 76 per cent of the weight of ingots reported. On account of the discard involved in shell steel production the percentage of rolled steel may have declined a trifle, but 75 per cent is a safe factor to use, and this would mean 3,000,000 net tons of finished rolled steel a month when ingots are being produced at 43,500,000 tons a year. With at least 1,160,000 tons involved in shell steel, plates and tin plates the operations of other finishing departments must be light.

There is a very interesting coincidence, that plates, structural shapes and tin plates are not carried in stock by mills, wholesalers or retailers to any extent. Merchant bars, pipe, wire products and sheets are normally carried in stock. At any one time there is a very considerable stock in the country. There is no scarcity of these materials from the standpoint of carrying on the war, but there is a possibility, with the continued restriction in output, that eventually a serious shortage will come to light. The steel industry has responded quickly and fully to the peculiar demands of war. The probabilities are that these demands will continue and may even increase, but should they slacken there is a reserve of demand for steel in replenishing the stocks throughout the country, now being depleted.

### Oil Shales, Albertite and Paper Shales

To the Editor of *Chemical & Metallurgical Engineering*

SIR:—In the interesting article published in your June 1 issue on "The Economic Position of Oil Shales" by Jac. C. Morrell and Gustav Egloff certain errors occur.

On page 603 appears a reference to "albertite, an oil shale from New Brunswick, Canada, known as paper shale." I desire to point out that albertite is not an oil shale nor has it ever before been so called or known as "paper shale." Albertite is solidified oil, found in a vertical vein that cuts through the many beds of shale found in the valley of the Frederick Brook and known as the Albert Mines.

Many years ago the albertite in the vein was mined. The mineral was said to have an analysis as follows: Volatile matter 54 per cent fixed carbon over 45 per cent, and ash only 0.17 per cent. On retorting it is claimed that the albertite yielded crude oil of from 100 imp. gallons to 130 imp. gallons per ton. The paper shales of which there are large masses exposed in the banks of the Frederick Brook yielded the following:

- A. 32 Imperial gallons oil and 38 lb. sulphate of ammonia.
- B. 34 Imperial gallons oil and 38 lb. sulphate of ammonia.
- C. 42 Imperial gallons oil and 38 lb. sulphate of ammonia.

Besides the large masses of paper shales, there are also exposed distinct beds of black and curly shale, which yield as follows:

1. 41 Imperial gallons oil and 39 lb. sulphate of ammonia.
2. 63 Imperial gallons oil and 52 lb. sulphate of ammonia.
3. 52 Imperial gallons oil and 73 lb. sulphate of ammonia.
4. 42 Imperial gallons oil and 52 lb. sulphate of ammonia.

All these analyses were made in the laboratory of the Department of Mines, Ottawa, and are more correct than those given in Table VI, where the results of samples from Albert Mines and from the Frederick Brook are given separately (in some cases probably duplication has occurred) whereas all belong to the same property, viz., Albert Mines. It will be noted that these results are markedly different from the results obtained from shales in Scotland, where the paper shales are not considered to be of economic importance, and where the shales that are low in oil content are usually high in the yield of sulphate of ammonia.

Nor is it correct to claim that the paper shale contains considerable quantities of fish remains; nor can the presence of the fish remains, as present in the Albert Mines shales, prove the origin of the hydrocarbons. It is true that in one exposure of one of the beds of the paper shales, which at this point are so badly crumpled that at first it would appear as if the whole formation has been tilted on end, there are

considerable of such remains. Their presence is, of course, interesting, but as "one swallow does not make a summer" so the presence of fish remains in the outcroppings of one bed of shale, of small thickness, would in my opinion if anything, tend to prove that the hydrocarbon contents of other beds of shale did not owe their origin to the remains of fish. Why should the remains be plentiful in this one thin bed and yet be entirely or almost entirely absent in the many other beds, all of which yield oil in considerable quantities.

So far as I am aware the shale from the bed that contains these remains has never been analyzed. Some day, as a matter of scientific interest, I hope that the shale of this bed will be analyzed and also of the beds above and below, in which no remains are found.

In the second article by the same authors in your issue for July 15 I call your attention to the comparative statement given on page 95, clause 6, of the general summary on the same page, and clause 12, page 96.

Apart from the fact that the statement as made is of no practical value, because averages so made can be manipulated, the comparison is unfair to Scotland and Canada.

The U. S. gallon runs 42 to the barrel. The gallon used in Scotland and Canada runs only 35. Since the average given for Scotland is (though not so stated) the Scotch average in Imperial gallons and since it is improbable that the authors would use the Imperial gallon for the results obtained by them from United States shales, it is evident that the returns for Scotland and Canada should be increased by one-fifth in order to compare fairly with U. S. returns. This would make the returns from Scotland 27.6 U. S. gallons and from Canada 41.9 U. S. gallons.

Clause 6 in the general summary requires correction for the same reason. Clause 12 suggests that the writers have small knowledge of the industrial end of the oil question. As California, Texas and Mexican crude oils are different from the crude oils of Pennsylvania, so are the oils retorted from the shales of one deposit different from those of another. Oils from one bed are different from oils of another and the oils from the same shales will vary with retorting in different retorts. I wish to say also that the laboratory retort heated by the Bunsen burner is not satisfactory for precise work, which should be undertaken in retorts in which the heat control can be better governed.

LOUIS SIMPSON.

Ottawa, Can.

### The Economic Position of Oil Shales

To the Editor of *Chemical & Metallurgical Engineering*

SIR:—The following addition should be made to our recent article on oil shales appearing in your issue for June 1, 1918, page 603:

To the section on the origin of petroleum should be added the highly interesting theory developed by Dr. Clifford Richardson\* that "the origin of petroleum is to

\**Jour. Ind. and Eng. Chem.* 8, 4, 1916; *Met. and Chem. Eng.* 16, 1917. (Jan. 1).

be attributed to the relation of surfaces and films of certain natural gases, either as a gas under pressure, at the levels where it exists, in a liquid state, to surfaces of solids, the oil 'sands' with which the former comes in contact." This theory seems to indicate that a highly catalytic and colloidal action takes place between the surfaces and films of certain natural gas to solid surfaces forming petroleum oil. The uniqueness of the theory has resulted from years of observation and experimental data along bituminous and natural gas lines, emanating from the Trinidad fields of which the latest gas samples show the constituents to be:

## FROM SURFACE OF ASPHALT DEPOSIT

|                                                                              | CH <sub>4</sub> | C <sub>2</sub> H <sub>6</sub> | CO   | N   | H <sub>2</sub> S |
|------------------------------------------------------------------------------|-----------------|-------------------------------|------|-----|------------------|
| Centre of Lake.....                                                          | 85.1            | 4.1                           | 9.8  | 0.0 | 0.0              |
| Where gas bubbles issue violently from centre of lake.....                   | 74.2            | 4.0                           | 20.0 | 0.0 | 0.8              |
| Where small bubbles issue gently from surface of water at centre of lake.... | 64.7            | 4.7                           | 26.3 | 0.0 | 2.7              |
| 1 Ibid.                                                                      |                 |                               |      |     | 1.6              |

It will be important to learn of Dr. Richardson's experimental verification of his theory, for with catalytic and colloidal phenomena playing their rôle in the origin of petroleum, the laboratory should speed nature's work and furnish us with bituminous material in measurable time from natural gas of certain composition. The results of Bardwell, Berryman, Brighton and Kuhre<sup>1</sup> have been brought into question and the following data corrections noted. Samples of the hydrocarbons under discussion (by Dr. Richardson) were reanalysed by T. B. Brighton and by the N. Y. Testing Laboratory with the following results:

| N.Y.T.L.                                 | Trinidad Per Cent | Bermud-z Per Cent | Talalyts Per Cent |

JAC C. MORRELL AND GUSTAV EGLOFF.

## Organic Reagents for Research Purposes

To the Editor of Chemical & Metallurgical Engineering

SIR:—In order to provide for the supply of organic reagents for research and industrial purposes the Eastman Kodak Company has determined to commence their preparation in its research laboratory.

This decision was arrived at as a result of the articles published by Dr. Roger Adams and of a recent letter by Professor Gortner in *Science* (June 14, 1918, p. 590), which drew our attention to the need for an adequate supply of these materials produced by a firm of standing.

In order to carry on the work a separate section of the laboratory has been established under the title of the "Department of Synthetic Chemistry," which will be under the immediate direction of Dr. H. T. Clarke, well known for his publications on organic chemistry.

In order to make available to research laboratories in this country the organic chemicals which they require, it is proposed that chemicals for research work shall be supplied at the lowest possible price. At first, no doubt,

this price will necessarily be higher than that charged by the German firms before the war, but it is hoped that eventually the profit made on chemicals supplied for commercial purposes may enable the rarer materials made in small quantities for research work to be sold at a price which will be within the reach of all who require them.

At first, of course, the laboratory will be able to supply only a limited number of substances, and these in small amounts, but the department will be expanded to meet the demand and with the assistance of other laboratories interested in organic chemistry, and of the firms who are producing dyes and intermediates, it is hoped that after a time an adequate supply of synthetic organic reagents can be made available.

It is possible that laboratories may have in stock unusual reagents which they are unlikely to require. If any laboratories possessing such reagents will write to us we shall be glad to make an offer for the materials, thus making them available on the market.

Our thanks are due to many of the chief chemists of the country who have encouraged us to commence this work and especially to Professor Roger Adams for the way in which he has received our proposals and has assisted us by placing at our disposal the information as to this work which he has accumulated.

Communications regarding reagents should be addressed to the Research Laboratory, Eastman Kodak Company, Rochester, N. Y.

C. E. K. MELES.

## Conforming to the Prior Art in Flotation

To the Editor of Chemical & Metallurgical Engineering

SIR:—During the past fifteen months Mr. Parker C. Choate has made four communications to you, the last three dwelling particularly upon the equities involved in the Minerals Separation litigation.

It seems to me that Mr. Choate, as I read his communications, has a wrong impression as to the attitude assumed by those using oil in excess of Minerals Separation patent. He is apparently under the impression that the use of oil in excess of the patent is considered by them as "a new process." He says in his communication of May 1, 1917 (*Met. & Chem. Eng.* Vol. 16, page 469):

"They talk of a new process, yet perhaps there is no technical reason why more than 1 per cent of oil gives better results, but merely the commercial reason to avoid royalty payment to a capitalized patent interest that must be fought, right or wrong."

And again in his communication in the current issue, July 15, 1918 (*Chem. & Met. Eng.*, Vol. 19, page 60) he says:

"If it were shown by defendants that there was an advance in the art, or a new process discovered by the use of oil, in any way, in excess of a fraction of 1 per cent, then the ruling of the California Court would be understandable."

Mr. Choate appears to be under the impression that Minerals Separation holds the basic position, that they

<sup>1</sup>Ibid.<sup>2</sup>*Jour. Ind. and Eng. Chem.* 5, 973, 1913, and 6, 565, 1914.

<sup>3</sup>March 1st, 1917, "Research and Industry," Vol. 16, page 241.  
 May 1st, 1917, "Evolution of Patent Suit Decisions," Vol. 17, page 459.  
 Oct. 15th, 1917, "Invention & the Flotation Suits," Vol. 17, page 452.  
 July 15th, 1918, "The Recent Flotation Decision," Vol. 19, page 60.

are the prior art. The fact is that the oil in excess of a fraction of 1 per cent was used by defendants to conform to the prior art and was frankly so stated. No claim whatever was made to "a new process" and there was no such "talk" by the defendant.

The court in San Francisco found no such distinction between efficient and non-efficient oils, as Judge Bourquin apparently injected into the patent. Everson had claimed oils and fats and fatty acids very broadly, and patent 835,120, of Minerals Separation, was no less broad as to the character of oil, simply claiming novelty as to quantity of oil used and manner and time of agitation.

Mr. Choate is absolutely wrong when he states that the decision of the Delaware court was sustained by the Supreme Court.

The U. S. Circuit Court of Appeals, in Philadelphia, reads the Supreme Court decision very differently from Mr. Choate. In the opinion of these judges the Supreme Court found the process of the patent to consist of an agitation greater than that of the prior art, in combination with a "critical" proportion of oil, and producing a froth different from that theretofore produced, whereas Judge Bradford had found that reduction in the quantity of oil of the process, as compared with the quantity of the prior art, was so great, as to in itself constitute invention.

Wallingford, Conn.

## Metallurgy of Zinc

*To the Editor of Chemical and Metallurgical Engineering*

SIR:—Concerning the discussion along the same line as suggested in Mr. Parker C. Choate's contribution to the July 1 issue of the *CHEMICAL & METALLURGICAL ENGINEERING*, the interrogation arises: What are the fundamental problems in the retort metallurgy of zinc? They appear to be:

First, zinc sulphide must be desulphurized.

Second, zinc ore must be reduced to the metal at a temperature which is above the boiling point of the metal at ordinary pressure.

Third, the metal after reduction must be condensed to the liquid form. In so doing the very troublesome blue-powder is formed.

Making refined zinc is a different field, not being considered at present in the discussion. However, if the refined zinc is primarily or finally produced by retorting, the above three fundamental problems enter into its production.

Dismissing the subject of roasting as being a field by itself and not considering the lime-reduction process for the present, the subject resolves itself into the second and third problems, namely, reduction and condensation.

In regard to reduction in a furnace using vertical retorts mechanically fed and discharged, there could be no more difficulty than in the ordinary type of retort. An idea for changing the retort would be to have a central core connected with a plunger which would raise the retort out of the combustion chamber when a change was needed. The matter of briquetting could also be worked out for this type of retort. In the issue of *METALLURGICAL & CHEMICAL ENGINEERING* for June 1, 1916, was published a description with a cut of such a

furnace being operated in Germany. It would not be surprising if some such research had been conducted in Belgium before the war.

As to condensation and the formation of blue-powder using a vertical retort, the conditions would seem to be more favorable to success than with the continuous electrothermic furnace with which a great deal of trouble was experienced along this line, for small units would still be used.

From a theoretical standpoint the metallurgical difficulties arising in reduction and condensation would be fewer in the vertical than in the old style retort. The principal inventions would have to be in devices for feeding and discharging the retorts.

The best process is the most economical. The most economical is the one with the least cost as to labor, maintenance, and fuel. In choosing a process it is necessary to nicely balance the three items of cost, one against the other. If the vertical type of retort with mechanical equipment is adopted, the labor cost will be reduced and the maintenance cost will increase. But it is doubtful if the increase of upkeep cost will overbalance the decrease in labor cost. This is a natural trend in all industries, and it seems that the zinc smelters should be doing profitable research work along this line.

In regard to the third item of cost, fuel, a question arises whether it will be easier to conserve fuel in using the old retort process or the vertical retort and mechanical equipment. It would appear that the latter would be more favorable for the reduction of fuel expense, because to reduce the extraneous coal, gas must be burned in small burners and thus be better controlled. To do this there must be conditions that call for uniform heat continuously. This will also allow the gas formed in reduction of the charge to be recovered from the condenser and used for fuel, as the temperature being uniform at all times the furnace man will not need to leave the gas burning at the end of the condenser to show how the furnace is running by the way it "lights up."

The conclusions are that the continuous process with the use of vertical retorts and a mechanical equipment will reduce the labor and fuel expense and increase the maintenance, but that it will result in a cheaper process, since the reduction of the two items of expense will more than balance the increase in the one.

J. H. HASTINGS.

Donora, Pa.

## Sugar Consumed by the Allies

The Food Administration has authorized publication of the annual statistics on sugar given below. It will be noted that America uses sixty per cent of this "human fuel" at a price very much below the average for Europe.

|                      | Tons Consumption | Price | Value         |
|----------------------|------------------|-------|---------------|
| United States .....  | 4,109,300        | \$146 | \$681,956,500 |
| United Kingdom ..... | 1,565,600        | 252   | 394,531,000   |
| France .....         | 370,600          | 246   | 140,372,766   |
| Canada .....         | 352,200          | 166   | 58,465,200    |
| Italy .....          | 277,000          | 526   | 145,667,300   |

The refiners now receive \$26 per ton for refining, which is perhaps the lowest rate for an equivalent amount of processing in the chemical industry. Large production makes this possible.

## Western Chemical and Metallurgical Field

### Tungsten Production, Imports and Requirements

AT THE conference held in San Francisco June 28 between the Tariff Commission and those interested in the production of tungsten, Mr. J. H. Mackenzie, of the Bureau of Mines, gave some interesting data on imports for 1917, together with data as to the origin and declared cost, c.i.f. New York. The imports of tungsten for 1917, figured to a basis of 60 per cent  $WO_3$  were:

| Origin                  | Amount (Tons) | Cost per Unit |
|-------------------------|---------------|---------------|
| Hong Kong               | 32            |               |
| China, other than above | 196           | \$11.60       |
| Siam                    | 28            |               |
| Japan                   | 603           | 17.70         |
| Mexican                 | 340           | 8.70          |
| Portugal                | 120           |               |
| Argentina               | 215           | 19.00         |
| Chile                   | 1,930         |               |
| Peru                    | 1,200         |               |
| Panama                  | 159           | 15.75         |
| Equador                 | 11            |               |
| Bolivia                 | 45            |               |
| South Africa            | 1             |               |
|                         | 4,880         |               |

It was understood that the Chinese production came mostly from the interior; Japanese imports largely originated from Manchuria and Korea, and possibly were in part byproducts of other milling operations. Little information as to the origin of the Mexican importations was available, but on account of its low price, it was suggested that at least some of it represented loot acquired by Sonora bandits. The exports from the ports of Chile, Peru, Panama and Equador were largely of Bolivian origin, where much of the production is won from placers. Portugal produces about 3000 tons of concentrate yearly—probably 1000 tons of this is smuggled into Spain and thence into Germany as this amount seems to be lost to regular trade channels.

The three large producers of tungsten are Burma, Bolivia and the United States, each with about an equal volume. The entire Burmese output goes to England, which government has recently raised the price from 55 to 60 shillings, as the cost c.i.f. Liverpool is quoted at \$15.25 per unit. The Siamese and Burmese deposits are quite similar, and on account of proximity may be extensions of the same mineralized horizon. The tungsten is mainly brought in by Chinese and Japanese coolies who go into the interior and collect the rich surface ore running as high as 70 to 75 per cent  $WO_3$ . The labor cost is very low—in the interior Chinese boys of 14 or 15 being had for about \$2.00 per month. The government tax is high, being from 30 to 40 per cent of the value, depending largely upon how many officials see it. Transportation and the sacks represent the balance of the importing cost, which would be from \$15.00 to \$17.00 per unit in the States.

Mr Mackenzie also tabulated the United States production (basis 60 per cent  $WO_3$ ):

|      | Tons                   |
|------|------------------------|
| 1908 | 671                    |
| 1909 | 1,619                  |
| 1910 | 1,821                  |
| 1911 | 1,339                  |
| 1912 | 1,330                  |
| 1913 | 1,537                  |
| 1914 | 990                    |
| 1915 | 2,352                  |
| 1916 | 5,849                  |
| 1917 | 4,800 or a little more |
| 1918 | 4,250 estimated        |

As shown, he thinks our probable production will be a little less this year than last, with greater imports.

The latter amounted to 595.5 tons per month for the first quarter of 1918, largely from South America, China and Japan, as compared to the monthly average of 400 tons in 1917. If production and importation is maintained at the above figures the available supplies of 60 per cent concentrates for 1918 will amount to 11,400 tons, against an estimated consumption of 11,975 tons.

Reports from sixteen large producers show their stock on hand as of May 1, 1917 and 1918, as follows:

|                                            | May 1, 1917<br>Pounds | On Hand<br>May 1, 1918<br>Pounds | Increase<br>Per Cent |
|--------------------------------------------|-----------------------|----------------------------------|----------------------|
| 70 per cent ferro-tungsten                 | 517,172               | 545,575                          | 5                    |
| Ore and concentrates                       | 1,134,379             | 2,370,219                        | 52                   |
| High speed steel                           | 3,555,257             | 5,269,958                        | 33                   |
| The total equivalent to 60 per cent $WO_3$ | 3,690,720             | 5,757,640                        | 36                   |

The main use for this metal is in the manufacture of high-speed steels, for which there is no substitute known. Valve stems and seats for aeroplane engines bid fair to absorb a considerable tonnage. Probably other quantities are absorbed in gun tubes, although information as to such uses is naturally scarce. Molybdenum has often been spoken of as a substitute for tungsten; however, Taylor's original work condemned molybdenum as a constituent in high-speed steel, as has recent British and French ordnance tests. These results are possibly largely responsible for the present dull market in tungsten substitutes.

### The Pacific Electro Metals Company

IT IS very natural for the Pacific Coast to become interested in electrometallurgy. The coastal regions, especially the California part, are well mineralized with various ores suitable for reduction in the electric furnace. Much hydro-electric power is already developed

FIG. 1 FERRO-SILICON FURNACE

and there are still large amounts of undeveloped power available comparatively close to tidewater. The Pacific Electro Metals Company has taken advantage of these conditions; the fact that it is being financed by a group of local men is an indication that the Pacific Coast is becoming awakened to the possibilities of new development aside from mining and agriculture. Its situation at Bay Point, Cal., is peculiarly fortunate in regard to transportation facilities, being served by two transcontinental railways as well as by deep-water navigation in Suisun Bay.

At the present time the furnace shown in Fig. 1 is in operation making a steel deoxidizer called silico-manganese of about the following analysis:

|    | Per Cent                 |
|----|--------------------------|
| Si | 20 to 25                 |
| Mn | 50 to 55                 |
| P  | 0.1                      |
| S  | Trace                    |
| C  | Less than 1, usually 0.5 |
| Fe | Balance                  |

The charge consists largely of a silicious ore of manganese, reduction being effected by the carbonaceous residue which was obtained from oil-gas works in the vicinity.

As shown in the illustration, the electric furnace is a three-phase furnace with an open top, lined with firebrick and carbon. Raw materials are kept heaped by shovel and rake around the electrodes, while the metal and slag are tapped at 2-hour intervals into sand beds formed in the car bodies, shown directly in front of the furnace. The operation of smelting is thus a continuous one. Transformer equipment for one furnace is composed of four single-phase, 1000-kw. transformers, one of which is a spare. The high tension current approximates a voltage of about 23,000, while the current fed to the furnace is in the neighborhood of 70 volts. The transformer room is a substantially built, reinforced-concrete addition immediately behind the furnace. Carbon electrodes are used and are 24 inches, round or hexagon. The holders are raised from time to time as the electrodes are consumed and the water-cooled clamps approach the ore charge, this operation consuming only about 10 minutes. Splicing being impracticable, the butt ends are reformed into the hexagonal electrodes stacked on the furnace room floor as in the illustration. This work is done in a well-equipped plant on the property. Much experimental work on a large scale has been done in this plant leading to the utilization of the gas-house carbon as a raw material for electrodes.

A second furnace of the same design is under construction in which ferro-manganese or silico-manganese will be made, according to the market. The furnace, transformer, packing and electrode buildings are all substantially built of concrete and impress the casual visitor very favorably. The site also contains warehouse, office, laboratory and other auxiliary buildings. The company has erected a colony of attractive cottages for their operators in the town of Bay Point.

Mr. J. Grotzinger is general superintendent of the company and in charge of the smelting operations. The plant was built during the last 12 months under the direction of the consulting engineers of the company, The Beckman & Linden Engineering Corporation of San Francisco, California.

**American Smelting and Refining Company.**—This company enjoyed a gross income of \$31,602,615 during the year ending Dec. 31, 1917, a record year, exceeding the maximum corresponding value by nearly three and one half millions. Net earnings applicable to dividends amounted to \$18,495,625 or 22½ per cent on common stock, after preferred dividends had been deducted. In the face of these returns, President Daniel Guggenheim notes that the peak price of metals was passed during the first half of the year, while costs of materials and labor are yet rising, and remarks: "By these two Governmental actions, first by reducing the value of our

product, and second, by constantly increasing our cost, this great corporation, producing what is absolutely necessary to the Government in carrying on the war, is having its ability to pay a fair return to its stockholders seriously jeopardized." During the year approximately \$4,700,000 was expended in extensions to smelters at Garfield, El Paso, and Hayden, and refineries at Baltimore, Perth Amboy and Tacoma, bringing the total capacity up to 1,150,000,000 pounds of electrolytic copper per year. An appropriation of \$6,000,000 was made for plant extensions and betterments during the year 1917, and the property account is now valued at \$136,797,476. During the year, the company added one more zinc plant to its operations located at Henryetta, Oklahoma. Poor railroad deliveries have resulted in a lock-up of values amounting to many million dollars, while severe weather and a shortage of labor have increased the difficulties of operation. Safety work costing \$160,000 has resulted in a 25 per cent decrease in the number of fatal accidents, a decrease of 451 disabling accidents, and a 5274-day decrease in time lost through temporary disability. The system of visiting nurses has been extended during the year, who visit workmen's homes, particularly in time of sickness, to instruct the mothers in the proper care of the family. Children's classes in sanitation and hygiene have also been organized.

#### OPERATING STATISTICS

|                                            | 1916          | 1917          |
|--------------------------------------------|---------------|---------------|
| Number of men employees, excluding Mexico  | 21,073        | 24,698        |
| Total wages and salaries, excluding Mexico | \$17,047,944  | \$24,497,836  |
| Average wages per 8-hour day               | \$2.70        | \$3.31        |
| Tons charge smelted                        | 4,789,474     | 5,918,924     |
| Tons bullion refined                       | 677,460       | 706,875       |
| Tons coal used                             | 724,595       | 787,890       |
| Tons coke used                             | 4,468         | 592,765       |
| Barrel fuel oil used                       | 1,107,285     | 1,560,555     |
| Cubic feet gas used                        | 2,130,460,328 | 3,032,908,373 |
| Tons ore mined                             | 1,638,566     | 2,318,925     |
| Tons coal mined                            | 244,807       | 259,490       |
| Tons coke produced                         | 140,961       | 186,107       |

#### METAL PRODUCTS

|                                        | 1916        | 1917        |
|----------------------------------------|-------------|-------------|
| Ounces gold produced                   | 2,662,011   | 2,496,693   |
| Ounces silver produced                 | 71,868,451  | 69,841,061  |
| Ounces platinum and palladium produced | 868         | 1,597       |
| Tons lead produced                     | 275,144     | 275,266     |
| Pounds copper produced                 | 789,438,000 | 848,888,000 |
| Pounds best select copper produced     | 42,807,547  | 66,086,000  |
| Pounds spelter produced                | 1,224,328   | 52,522,000  |
| Pounds nickel produced                 | 4,522,000   | 682,715     |
| Pounds tin produced                    | 4,522,000   | 12,130,000  |
| Pounds sulphuric acid produced         | 25,842,000  | 66,174,000  |
| Pounds arsenic produced                | 9,090,000   | 9,132,000   |
| Pounds copper sulphate produced        | 13,046,000  | 7,598,000   |
| Pounds by-product metals               | 5,671,827   | 4,131,709   |
| Pounds copper and brass manufactured   | 31,597,489  | 39,767,274  |
| Pounds steel lead and litharge sold    | 417,898     | 426,477     |
| Number loaded cartridges sold          | 15,338,000  | 14,180,000  |
| Pounds sheet lead, pipe, etc., sold    | 21,713,331  | 13,678,245  |
| Pounds mixed metals sold               | 2,631,617   | 5,168,045   |

### Graphite Crucibles Placed on List of Restricted Imports

The War Trade Board has placed graphite crucibles upon the list of restricted imports. All outstanding licenses for the importation of graphite crucibles have been revoked as to ocean shipments after July 15, 1918, and no licenses for the importation of this commodity for shipment after that date will be granted for the rest of the calendar year. Imports of graphite are already prohibited, the result of this restriction having been to develop an adequate supply of graphite within the country. The action of the War Trade Board in restricting the importation of graphite crucibles is complementary to the restriction upon the importation of graphite.

## Alien Property Custodian Seizes Metal Concerns

IT WAS announced on July 22 that the Alien Property Custodian had seized the property of L. Vogelstein & Co., Beer, Sondheimer & Co., and other minor organizations engaged in the metal industry. These were German-owned firms which exercised a large influence in the world's metal business. According to the Alien Property Custodian these firms had taken advantage of certain legal advice which had enabled them to masquerade as American firms so successfully that months of investigation were required to prove enemy ownership. Both of the seized corporations had made reports stating that they were American-owned, but apparently the Americanization was only a surface effect designed to hide German ownership. The following statement was issued by the Alien Property Custodian: "With the American Metals Company, the large enemy interest in which has already been taken over by the Alien Property Custodian, Beer, Sondheimer & Co. and L. Vogelstein & Co. controlled most of the principal metal and smelting companies of this country, either by complete ownership of stock or by the ownership of enough stock to give them substantial representation on the Boards of Directors.

"Beer, Sondheimer & Co. own a one-half interest in the National Zinc Company, the entire stock of the Cuba Copper Company, the Cuba Copper Leasing Company, and the Norfolk Smelting Company, 30,000 shares of the Minerals Separation American Syndicate, Limited.

"Vogelstein & Co. have large holdings in the United States Metal Refining Company and the Kansas Zinc and Smelting Company. Of the 70,000 shares of capital stock of the American Metals Company, 15,180 shares are owned by the Metallbank and M. C. of Frankfurt-am-Main and 18,180 shares by the Metallgesellschaft of the same place.

"The American Metals Company completely owns the following companies: American Zinc and Chemical Company, Langeloth Coal Company, Langeloth Mercantile Company, Langeloth Townsite Company, American Metal Transport Company, Bartlesville Zinc Company, and South American Metal Company. It had large holdings of stock in the following companies: Ohio and Colorado Smelting and Refining Company, Compania Minera de Penoles, South America; Compania de Minerales y Metales, South America; Compania Metalurgica de Torreon, South America; Compania Minero Palome y Gabrillas, South America; Compania de Combustibles Agujita, South America; Fundicion de Guayaca, South America; Balbach Smelting and Refining Company, and Nichols Copper Company.

"In 1914 the profits of Beer, Sondheimer & Co. were \$116,624; in 1915 the profits of this concern jumped to \$1,013,676, and in 1916 they reached the large total of \$2,000,000. In 1917, after the United States got into the war, the profits dropped to \$196,900.

"The profits of L. Vogelstein & Co. since April, 1916, were extremely large, the firm's business for the last three years approximating \$70,000,000 a year. Between April and December of 1916 the profits of Vogelstein & Co. amounted to upward of \$2,500,000.

"To make these concerns 100 per cent American, the Alien Property Custodian has appointed as Directors Americans who are well known in the business and financial life of the country.

"The Directors named for Vogelstein & Co. are:

EDWARD M. McILVAIN, former President of the Bethlehem Steel Company.

LOUIS A. WATRES, President of the Scranton Trust Company and former Lieutenant Governor of Pennsylvania.

JAMES N. WALLACE, President of the Central Trust Company of New York.

ALFRED H. SMITH, President of the New York Board of Aldermen.

C. C. DANIELS of New York City.

"The Alien Property Custodian will allow Paul L. Vogelstein and Ernest Hethern to act as Directors also; Isidor J. Kresel, 37 Wall Street, New York City, will act as counsel for this company.

"Messrs. Wallace, McIlvain, and Watres will also act as Directors of Beer, Sondheimer & Co., in addition to John P. Greer, 15 Broad Street, New York City, and Ford Huntington, 15 Dey Street, New York City. Benno Elkan and Otto Frohnecht will act with the above Directors. Joseph E. Davies, former President of the Federal Trade Commission, and Isidor Kresel will act as counsel for this company.

### DIRECTORS FOR AMERICAN METALS CO.

"The Directors whom the Alien Property Custodian has selected to represent the enemy interest in the American Metals Company are:

HENRY MORGENTHAU, Former Ambassador to Turkey.

ANDREW W. MALLON of Pittsburgh.

GEORGE MCANENY of New York City.

LEWIS L. CLARK of the American National Bank of New York.

E. C. CONVERSE of the Bankers Trust Company of New York.

"John J. Fitzgerald will act as counsel. Mr. Wallace, with Francis P. Garvin, have been chosen by the Alien Property Custodian to act as Directors for Stallforth & Co."

## Government Controls Chlorine Production and Distribution

The War Industries Board authorizes the following: Owing to the shortage of chlorine in the United States, the War Industries Board, with the approval of the President, has passed a resolution taking over control of its production and distribution. For the present, however, the board is doing no more than allocate the product, and this is being done under the direction of H. G. Carrell, chief of the Alkali and Chlorine Section of the War Industries Board.

Chlorine has a wide range of uses, the most important from the present Government point of view being in the manufacture of gas shells and in carbon tetrachloride, which is the basis of one of the most effective smoke screens and also of the best fire extinguishers.

One of the most important commercial uses of chlorine is in the bleaching of paper and various cloth fabrics.

## Platinum as Seen by the Jeweler and the Chemist

AT THE hearing with reference to the new revenue bill, held before the Committee on Ways and Means at Washington on July 10 and 11, the subject of platinum received considerable attention. It developed however, that most of the testimony resolved itself into a controversy between the jeweler and the chemist, rather than enlightening the Ways and Means Committee as to methods of deriving revenue by taxing platinum.

MR. MEYER C. ROTHSCHILD of New York City, representing sixty-two jewelry organizations in the United States, appeared before the committee on behalf of the jewelers. Much of his testimony was devoted to a reply to a speech made by the Honorable Henry T. Rainey, of the Committee on Ways and Means, on the floor of the House of Representatives on June 7. Mr. Rothschild felt that Mr. Rainey had put the jewelers in the wrong light before the country. He also felt that the campaign conducted by the American Chemical Society through the *Journal of Industrial and Engineering Chemistry* had misrepresented the platinum situation as far as jewelers were concerned with it. He stated that the Jewelers' War Service Committee had called on the War Industries Board at Washington, and had recommended that all unmanufactured platinum held by jewelers be commandeered. The War Industries Board, however, felt that this would seriously disturb the jewelry industry and consequently they commandeered 75 per cent of the stock of unmanufactured platinum in the hands of jewelers, after having been unsuccessful in getting the jewelers to give up their stock voluntarily. Mr. Rothschild took the position that the government should have commandeered platinum long before it did, taking no chances in regard to having an adequate supply. In cross examination of Mr. Rothschild, Congressman Longworth introduced a copy of a jewelry magazine showing full-page advertisements in which platinum jewelry was featured. The advertisements were cited as an example of what had not been accomplished in the direction of preventing advertisements of platinum jewelry.

Whatever may be the merits or the demerits of the jewelers' attitude, Mr. Rothschild made some remarks in regard to the attitude of the War Industries Board in fixing a price of \$90 per ounce for platinum when it was selling in the open market in New York at \$105.

Mr. Rothschild pointed out that but for the unbusinesslike attitude of the War Industries Board, the United States might easily have secured additional platinum supplies from Russia. This, however, was impossible when a price of but \$90 per ounce was paid for some 21,000 ounces which was brought over here at great risk. Mr. Rothschild was of the opinion that there was about one million ounces of platinum now in the country, of which the jewelers held a stock of about 5000 ounces on February 1, 1918.

DR. CHAS. H. HERTY, editor of the *Journal of Industrial Engineering Chemistry* appeared before the committee to correct certain erroneous impressions which he felt were created by Mr. Rothschild. Doctor Herty pointed out particularly that the movement started by the American Chemical Society for the conservation of platinum was not a propaganda on the part of a few

chemists, but the action of an important organization embracing about 12,000 chemists in every part of the country. Doctor Herty showed the essential nature of platinum in the chemical industry and its unessential use in jewelry, particularly in war time, and defended very well his entire editorial campaign against such use of the metal.

On the question of taxation of platinum, it was Dr. Herty's opinion that there should be none of the metal available for taxation; that the Government should purchase the entire supply in this country and place it in the vaults of the Treasury for Government needs. He pointed out that there was a great deal of manufactured platinum jewelry in this country today, which could easily be bought by pro-German interests and transmitted to Germany in a round-about way.

DR. LOUIS J. WEINSTEIN of the Dental Department of Columbia University, also appeared before the Ways and Means Committee, with regard to the use of platinum in the dental business. He was of the opinion that the dentists of the United States use about 20,000 ounces of platinum per year, but that this quantity could be reduced very materially through the use of substitutes. He felt that on a request coming from an authoritative source, the use of platinum could be cut down so that only one-fourth of the customary amount would be used in dentistry, which would release about 15,000 ounces per year for other purposes.

MR. LELAND L. SUMMERS of the War Industries Board appeared before the Committee to refute the inference carried by previous testimony that the War Industries Board "has been incompetent and asleep, and that the military program of the Government has been imperiled" thereby.

Mr. Summers explained the Board's policy in fixing \$90 per ounce as the price to be paid for the 21,000 oz. of Russian platinum by saying that the British Government official price was only \$65 per oz. and that our Government commandeered the Russian lot at \$90 with the understanding that those who had furnished the platinum could go before the Court of Claims or the Board of Appraisers and get more if they could show that \$90 was not a fair price.

Mr. Summers upset all previous testimony by saying that the agitation about platinum has been overdone; that he was not distressed as to where the platinum is coming from; and that substitutes could be used just as they have been elsewhere. He stated emphatically that "we are not up against any crisis." The War Industries Board now controls 40,000 oz. of platinum, and apparent requirements on March 1, 1918 were 37,000 oz. and today about 55,000 oz. The apparent shortage can be provided by supplies from Colombia, 10,000 oz. from Great Britain, and by extending the commandeering orders not only to the jewelry trade but also to the dental and chemical professions. With regard to substitutes for platinum for making sulphuric acid, Mr. Summers stated that "we are getting very satisfactory results from preliminary experiments that have been undertaken."

With regard to further extension of the commandeering orders, Mr. Summers said that by including the chemical and dental industries and the balance of the jewelers, provision would be made for our requirements well into 1920.

## New Government Agency Taking Census of Industries

To meet the constantly increasing demands of the Government for new resources and to supply the War needs of the Army and Navy and other Government departments, the War Industries Board has created the Resources and Conversion Section.

The primary object of this new section is to assemble as quickly as possible complete and detailed information concerning industries in all parts of the country:

- (a) Those not now engaged in war work but capable of undertaking such work.
- (b) Concerning industries only partly employed on war work but able to increase their production of necessary war materials, and
- (c) Industries now employed on war work whose contracts will soon be complete.

To accomplish this in the most efficient way it has been decided to divide the country into regions and organize them thoroughly under the leadership and with the co-operation of the local Chambers of Commerce and other business men's organizations.

It is desired to enlist the aid of all classes of industry, and to bring this about it is imperative that all

As an indication of what is possible in the conversion of industry to meet war requirements and of the changes which can be made in the product of a factory, a few radical instances serve to illustrate. For instance, a Pennsylvania factory that formerly made linoleum is now machining 4.7-inch shells. A Duluth horseshoe manufacturer is turning out trench picks for the Army, and a New Jersey terra-cotta tile concern is making dummy drop bombs. A Milwaukee factory, the former output of which was rowboat motors, is making hand grenades and trench pumps. In Rhode Island, a manufacturer of finger rings has returned his activities to making adapter plugs. A Detroit stove concern is producing trench bombs and anchor parts, and a New York shirtwaist manufacturer is making signal flags.

## Corporation Organized to Sell Enemy-Owned Property

The formation of a selling corporation to control and sell all German-owned corporations taken over by the Alien Property Custodian has been announced at Washington. This selling corporation will have complete control over the sale of nearly 150 enemy-owned corporations now in the custody of the Alien Property Custodian, valued at about \$250,000,000.

In addition to the Alien Property Custodian the new selling organization will consist of a Washington committee, an advisory committee in New York, a sales manager in New York, representatives of the Alien Property Custodian in charge of each property to be sold, and an attorney representing the Alien Property Custodian in respect of each property to be sold. Sales will be made at public auction whenever it is possible to do so, and unless the Advisory Committee recommends different procedure. This applies not only to sales by the Alien Property Custodian, but also to sales by and in the name of

corporations controlled by him. The expenses of each sale, which shall include all expenses and costs of every kind, shall be paid out of the funds of the specific property sold, or out of the purchase money received from such sale, or deducted from the purchase price.

UNITED STATES INDUSTRIAL REGIONS

the industries of a given region should be asked to participate whether they are now members of business organizations or not.

The twenty regions and the regional representatives appointed are:

| Region No. | Region        | Name                 |
|------------|---------------|----------------------|
| 1          | Boston        | Stuart W. Webb       |
| 2          | Bridgeport    | B. D. Pierce, Jr.    |
| 3          | New York      | Wm. F. Morgan        |
| 4          | Philadelphia  | Ernest T. Trigg      |
| 5          | Pittsburgh    | George S. Oliver     |
| 6          | Rochester     | Eaton A. Fletcher    |
| 7          | Cleveland     | Win. B. McAllister   |
| 8          | Detroit       | A. H. Templeton      |
| 9          | Chicago       | D. F. Felt           |
| 10         | Cincinnati    | Edwin C. Gibbs       |
| 11         | Baltimore     |                      |
| 12         | Atlanta       |                      |
| 13         | Birmingham    | T. H. Aldrich        |
| 14         | Kansas City   | F. D. Crabbs         |
| 15         | St. Louis     | Jackson Johnson      |
| 16         | St. Paul      |                      |
| 17         | Milwaukee     | August H. Vogel      |
| 18         | Dallas        | Louis Lipsitz        |
| 19         | San Francisco | Frederick J. Koester |
| 20         | Seattle       |                      |

## Instruction and Research in Industrial Hygiene at the Harvard Medical School

Through the foresight and generosity of a group of New England manufacturers, who appreciated the importance of studying the diseases peculiar to factory labor, special courses have been arranged, which will be given in the School of Public Health. Those properly qualified may matriculate for the degree of Doctor of Public Health (Dr. P.H.). For information apply to Dr. C. K. Drinker, Harvard Medical School, Boston, Mass.

## Distribution of Niagara Power

INTERVENTION by the United States in the control and distribution of power generated in this country in the Niagara Falls district and that imported from Canada has resulted in accurate knowledge of the uses of that power. In a report recently made to Secretary Baker by Brig. Gen. Charles Keller and Robert J. Bulkley, it is shown that practically all the power available is used to the advantage of the prosecution of the war, as appears in Table I.

TABLE I—THE USAGE OF ELECTRIC ENERGY AS PRODUCED DURING A TYPICAL PERIOD IN THE WINTER OF 1917-1918

|                                                              | Niagara Falls Power Co. | Hydraulic Power Co.        | Niagara, Lockport & Ontario Power Co. | Buffalo General Electric Co. |
|--------------------------------------------------------------|-------------------------|----------------------------|---------------------------------------|------------------------------|
|                                                              |                         | Percentage of Total Output | Power Company                         |                              |
| Direct war industries.....                                   | 73.53                   | 97.05                      | 58.31                                 | 50.27                        |
| Transportation purposes....                                  | 11.55                   | .....                      | 21.21                                 | 21.47                        |
| Street, commercial and residence lighting, water supply..... | 7.81                    | 1.95                       | 7.61                                  | 13.99                        |
| Commercial power consumers over 100 H.P.....                 | 1.52                    | 0.13                       | 5.94                                  | 2.82                         |
| Small commercial power....                                   | 3.61                    | 0.78                       | 6.80                                  | 7.49                         |
| Non-essential purposes.....                                  | 1.98                    | 0.09                       | 0.13                                  | 3.96                         |

Table II shows not only the increased allotments of power to the essential electrochemical industries in the Niagara district, but also the average amounts of

entials as ferrosilicon, electrodes, phosphorus, chlorine, and abrasives.

TABLE IV—DISTRIBUTION OF ELECTRIC POWER OF THE NIAGARA FALLS POWER COMPANY OF NIAGARA FALLS BEFORE AND AFTER APPLICATION OF ORDER OF THE SECRETARY OF WAR, DECEMBER 28

| Name of Company Taking Power     | Use of Power, Nov., '17 | Reapportionment of Power, Increase |                    | Distribution of Power, Mar., '18 |
|----------------------------------|-------------------------|------------------------------------|--------------------|----------------------------------|

## Mining Engineers Meet in Colorado in September

The American Institute of Mining Engineers will hold its regular Fall meeting in Colorado during the week of Sept. 2. The sessions will open in Denver on Sept. 2, after which headquarters will be at Colorado Springs.

TABLE II—NIAGARA FALLS—BUFFALO DISTRICT INCREASED ALLOTMENTS OF POWER TO ELECTROCHEMICAL INDUSTRIES IN APRIL 1918, AS COMPARED WITH POWER USED IN NOVEMBER, 1917, UNDER NORMAL CONDITIONS

<sup>1</sup> Later returned to Paper Company when it began manufacture of ferrosilicon

Trips will be made from that point to the Cripple Creek district, Pueblo, Leadville district and Boulder. The sections to be visited are rich in important war minerals and important in the manufacture of ferro-alloys. The committee in charge of the meeting comprises: Spencer Penrose, chairman; A. E. Carlton, chairman finance committee; George M. Taylor, vice-chairman; J. Dawson Hawkins, secretary. Denver committees: (Arrangement) Dave G. Miller, Frank Bulkley, Geo. E. Collins; (Entertainment) F. H. Bostwick, F. E. Shepard, Howland Bancroft, B. P. Morse, J. G. Perry; (Finance) T. B. Stearns, Richard A. Parker, T. B. Burbridge.

On July 1 670 officers and employees of H. M. Byllesby & Company and affiliated companies were engaged in the military service of the United States or Allies. This represents 13.8 per cent of all male employees. The service flag now bears four gold stars.

# The Metallography and Heat Treatment of Metals Used in Aëroplane Construction

Introduction to a Series of Articles Dealing With Cast Iron, Steel, Aluminium, Copper, Bronze, and Brass—Typical Examples of Investigations of Aëroplane Parts, With Microphotographs and Results of Physical and Chemical Tests

By F. GROTTES

Chief Metallurgist, Curtiss Aëroplane and Motor Corporation.

THE metals that are used in aëroplane construction are aluminium, copper, bronze, brass, cast iron and steel. Of these, steel has the most importance as more and important parts are made from it than from any of the other metals. It is divided into two classes, (a) carbon steel and (b) alloy steel to which has been added some particular element (Ni, Cr, V, etc.). The first division, carbon steel, is subdivided into low (0.15 per cent C), medium (0.32 per cent C) and high (0.9 per cent C); while the second division includes the nickel, chrome, vanadium, chrome-nickel and chrome-vanadium steels.

The structure and physical properties of these metals are greatly affected by the treatment or treatments, both mechanical and thermal, to which they have been subjected at the time of manufacture or after. As the structure and physical properties are of supreme importance it is necessary that they be investigated. This is done by certain tests, the best of which is a test to destruction, but this method is too expensive and time-consuming. Sometimes a practical field test will give all of the data necessary, but in order to judge whether or not a metal is suitable for the purpose for which it was intended, separate parts of the material are selected for test, and upon the results of these tests the metal is judged as a whole.

Chemical and physical tests give satisfactory data within certain limits, but they should be supplemented by metallographic tests which give information not obtainable by any other method. The particular use of metallographic testing is to give information in regard to the homogeneity of the metal, the heat treatment to which it has been subjected, and whether it has been subject to any strains.

## METHODS AND APPARATUS USED IN TESTING

In taking up the metallography and heat treatment of the materials before mentioned, the methods and apparatus will first be discussed.

**Preparation of Samples.** The samples used for metallographic examination are about one-half inch square or round. They are cut in most cases with a hacksaw, but hardened materials are cut with an emery wheel to the required size. Where the samples are too small to hold it is necessary to polish out to their edge; they are mounted in a section of tubing with solder or other low melting-point material. The tubing is about one-half inch long and one-half inch in diameter. The part to be mounted is placed in the center and the solder poured in the tube around it. This holds the specimen firmly and a good polish results.

**Polishing.** After taking the sample, all rough edges are removed with a file or emery cloth after which the section is ground down progressively from a coarse to fine emery belt and then, starting with No. 0 polishing paper, to No. 0000. At this point it is carefully examined to see if all scratches are removed; if so it is placed on a buffer covered with cloth and on which is placed some alumina and water. After this the specimen should be ready for the microscope.

### Rules for Polishing

1. Never overheat specimen and use light pressure.
2. Prevent the surface from becoming convex.
3. Turn specimen through 90 deg. after each separate operation and polish in the same direction during each operation.
4. Continue each step only long enough to eliminate the scratches of the previous operation.
5. Wash the specimens thoroughly between each operation to prevent particles of one abrasive from becoming mixed with the next and finer abrasive.
6. Keep all apparatus and solutions covered when not in operation. Fine particles, dust, sand, emery, etc., will spoil a half-day's work.
7. Use light pressure for aluminium, brass, bronze, etc., and in finishing on the buffer twist the specimen now and then to prevent smears or streaks in the direction of polishing.

**Etching.** Clean the section carefully with warm water and dry with alcohol. Immerse in the chosen solution for five seconds, ten seconds, etc., until etched properly. Clean with hot water and dry with alcohol. If the specimen is covered with a film, rub carefully on buffer and clean with alcohol. Etching solutions have the following composition: Nitric acid solutions of 10 cc. HNO<sub>3</sub> in 90 cc. alcohol and 20 cc. HNO<sub>3</sub> in 80 cc. alcohol are used. These solutions give good results but are not so good to show the structure for all steels in general as the following picric acid solution.

Picric acid: Saturated solution or about 10 grams of picric acid in 90 cc. of alcohol.

Sodium picrate: Two grams of picric acid is dissolved in 98 cc. of a solution of 250 grams of NaOH in 750 cc. of water. After boiling the polished specimen in this solution for 10 minutes, the ferrite remains bright while the cementite is dark colored.

Iodine: Tincture of iodine for copper, brass and aluminium, also to show strains in steel.

Copper ammonium chloride: For bronze and brass; 10 g. copper ammonium chloride, 15 cc. concentrated ammonium hydroxide, 250 cc. water.

**Heat Tinting.** Heat slowly until the specimen is colored yellow-brown, when the parts high in phosphorus will appear purple or blue.

**Sulphur Printing.** Velox printing paper soaked in a 3 per cent solution of sulphuric acid or 10 per cent hydrochloric acid solution is placed on the specimen for 20 seconds, washed in water and then fixed in hypo as are other prints. Sulphur shows black, due to the H<sub>2</sub>S given off from the reaction of the acid on the sulphide in the specimen. Care is taken to prevent specimen from slipping during printing operation.

#### PHOTOMICROGRAPHY

After polishing, the specimens are examined for slag, manganese, sulphide or pipes. The slag shows as dark irregular masses, the manganese sulphide as dove-colored oval-shaped bodies and the pipes as shown in Fig. 1.

After selecting the spot to be photographed, adjust the light carefully so as to get as bright and even

FIG. 1

illumination as possible. Focus the image as sharp as possible with the coarse adjustment and then finish with the fine adjustment.

**Exposure.** After the image is properly illuminated and focused, the plate is introduced and exposed. The length of exposure varies according to kind of plate, polish of specimen, power of illumination and color of screen (green, red, etc.). The plates used are panchromatic and Wratten "M" plates with green screen and electric arc illumination. The panchromatic plates are exposed for 15 seconds with the small orifice and the "M" plates for the same time with the next larger orifice.

**Development.** These plates are handled in an absolutely dark room and are developed for 15 minutes in Eastman developing powders 24-31-A-4 at a temperature of 65 deg., washed in cold water and immersed in fixing solution for 15 minutes.

Stock fixing solution

|                                        |     |
|----------------------------------------|-----|
| 384 oz., H <sub>2</sub> O              | } A |
| 96 oz., H <sub>2</sub> PO <sub>4</sub> |     |
| 30 oz., H <sub>2</sub> O               |     |
| 6 oz., Na <sub>2</sub> S               |     |
| 18 oz., Acetic acid                    |     |
| 6 oz., Alum                            | } B |

Add B to A slowly and stir vigorously.

After fixing, the plates are washed in running water for twenty minutes, then dried in a current of air.

**Printing Papers.** Velox regular glossy is used, printed for the necessary time to get the desired result, developed in solution of Eastman MQ developer at a temperature of 70 deg., washed in water and fixed in stock fixing solution for 15 minutes and then washed in running water for 20 minutes.

**Drying Papers.** A ferrotype tin is used which is first washed with water and dried with alcohol and then covered with a solution of beeswax in benzol. After drying, the surface of the tin is polished and the papers placed on it and rolled smooth. All moisture is removed with a blotting paper after which an electric fan soon dries the prints which drop from the tin and can be cut to the proper size and mounted.

#### HEAT TREATING

The object of heat treating is, first, to remove any stresses that might exist in the material; second, to refine and improve the structure; third, to cause a change in order to get the required physical properties. To understand these objects it is necessary to have considerable knowledge of the nature and composition of the metallic alloys. This is essential to an intelligent microscopic examination and heat treatment of any specimen of steel.

Steel is an alloy of various elements, the most important of which are carbon and iron. They go into solution at a high temperature while on cooling the constituents crystallize out in the form of octahedrons which have three cleavage planes showing in martensite.

In the heating and cooling of steel, certain phenomena are observed. For illustration; at one point, the steel becomes magnetic, and at another it seems to gain heat on cooling and actually glows. These points are called critical points and are shown by plotting cooling and heating curves.

**Critical Points.** In order to determine the proper heat-treating points, temperature curves are plotted which show the critical range. An easy method of procedure and accurate enough for most purposes is to take pieces of the material and place them firmly about a thermocouple in a furnace. As the heat rises, temperature readings are taken about every 10 seconds up to 1700 deg. F., which will take care of most steels. Plot the curve time and temperature, both heating and cooling. The material is quenched at about 100 deg. F. above the large break in the curve.

Where more accurate data are required, there is used a neutral body and a double thermocouple so connected that the difference of temperature between the metal under investigation and the neutral body is recorded as well as the actual temperature of the metal. This shows the critical range and whether there are one, two or three critical points. To distinguish critical points on cooling from those occurring on heating, the former are called Ar (from the French *refroidissement*, meaning cooling) and the latter Ac (from the French *chauffage*, heating). The points on heating are designated Ac, Ac<sub>1</sub>, Ac<sub>2</sub>, and on cooling as Ar<sub>1</sub>, Ar<sub>2</sub>, Ar<sub>3</sub>.

The Ar<sub>1</sub> points in the carbon steels used occur between 1250 and 1350 deg., and Ac<sub>1</sub> points about 75 to 100 deg. higher (all temperatures Fahrenheit). The critical points on cooling always lag behind the points on heating.

The critical points are due chiefly, if not wholly, to allotropic changes of the iron; and their great importance is due to the fact that the color, crystallization, dilation, conductivity for heat and electricity, strength, ductility, hardness and specific gravity of the steel are affected while passing through them.

There are three allotropic forms of iron: alpha, beta and gamma. Below the  $A_1$  point it is known as alpha which is magnetic, soft, and will not take any carbide into solution; between the  $A_1$  and  $A_2$  points is beta which dissolves carbide, is non-magnetic and harder than alpha iron. Above  $A_2$  is gamma which also dissolves carbide, is very hard and non-magnetic. The addition of different elements will influence the critical points. Manganese and nickel lower the critical points. Silicon and phosphorus go into solid solution with the ferrite and have no appreciable effect. Chromium and tungsten raise the critical temperatures and vanadium has no marked effect.

#### ANNEALING, HARDENING AND DRAWING OF STEEL

Steels are divided according to their carbon content into three classes: hypoeutectoid, below 0.89 per cent carbon; eutectoid, at 0.89 per cent; and hyper-eutectoid, above 0.89 per cent. The hypoeutectic class will cover most of the aeroplane steels. The medium carbon steel is a good illustration.

This material is generally in an annealed condition to start with, or a mixture of ferrite and pearlite. As heat is applied and the steel passes the  $A_1$  point, the constituents go into a solid solution consisting of iron carbide, cementite or a double carbide of iron and the special element, (Cr, V) in gamma iron. If this is quenched in salt water or other abrupt medium, it is called austenite, but if quenched in oil, probably martensite, which is a more stable form resulting from the austenite giving way along its cleavage planes. On heating or drawing martensite, there is a slight precipitation of ferrite or beta iron. This mixture consisting of beta iron and a solid solution of carbide in gamma iron is called troosite which becomes sorbite on further drawing or on a further precipitation of beta iron. At the  $A_c$  point the beta iron is converted into alpha iron and on the drawing being continued the gamma solution approaches the eutectic until at the  $A_c$  point it is converted into pearlite. The mixture now consists of ferrite and pearlite.

*Annealing.* The object of annealing is to relieve strains and to soften the structure or make it normal. It consists in raising the steel to a temperature above the  $A_c$  point and holding it a sufficient time to get a complete solid solution. Then allowing it to cool slowly in the furnace in order that all transformation may be completed—austenite, martensite, troosite, sorbite and ending with a mixture of ferrite and pearlite. This is a furnace or soft anneal.

Most annealing or better normalizing is done by merely heating past the  $A_c$  point and then cooling in air. This gives a mixture of ferrite and sorbite instead of ferrite and pearlite as results in furnace cooling. If a fine structure is wanted coincidentally in a good soft material, quench at above the  $A_c$  point and draw at just below the  $A_c$  point.

*Quenching.* Materials are quenched in order to get

maximum hardness and grain refinement. It consists in heating the steel past its  $A_c$  point and quenching in oil or water. This retains it in its austenitic and martensitic condition which is very hard and fine. See Fig. 2.

*Drawing.* Drawing consists in heating to some point below  $A_c$  and cooling in air or oil. This is a softening or toughening process in which ferrite is liberated varying with the increase of draw. Practically all of these steels on being drawn are sorbitic, as shown in Fig. 3.

*Grain Size.* Care should be exercised in not passing the upper critical too far, as the grain size grows accordingly and there is danger of overheating.

*Overheating.* This causes a very coarse structure but it can be restored by merely heating to a little above the critical (upper) point and quenching. Overheating should not be confounded with burning. Compare Figs. 4 and 5.

*Burning.* Burnt steel is brittle and its fracture is coarse and shiny. Material that has been burnt is of no value in this work.

*Test Specimens.* All specimens that are heat-treated for test purposes are carefully machined to the required shape and size, then treated in electric or oil furnaces. Much attention should be paid to the machining of specimens, as an extra deep cut will spoil the test. This often occurs near the shoulder. The data from a poor specimen are of no value.

#### FURNACES AND PYROMETERS

*Electric Furnaces.* The electric furnaces used are of Hoskins manufacture and give a good even heat up to 2000 deg. F. They are especially adapted to heavy duty or continuous operation and are capable of 24-hour-per-day service. The heating units of chromel in the shape of hair pins can be easily removed and replaced in a short time in case they are burned through. They operate on low voltage (10 to 57.5 volts) for which reason they are best adapted for use on alternating-current circuits in connection with a transformer. It takes about two hours to reach 1800 deg. F. from a cold furnace. The thermocouple enters at the center of the rear. In order that the material treated may be nearer the couple, a piece of sheet steel or secondary bottom is inserted. This is placed on small supports of sufficient height to bring the sheet within a distance of two inches of the couple. This sheet will also prolong the life of the furnace lining.

The atmosphere is oxidizing, so that at high temperatures care must be exercised to prevent excessive scale. It is sometimes necessary to inclose the samples in boxes or tubes in which has been placed some oil, kerosene, etc. The covers are sealed with fire clay.

Where a specimen is to be quenched at say 1500 deg. F. the furnace is slowly brought up from 1000 deg. F. over a period of about 30 minutes to 1500 deg. F. At this point the temperature is held for 10 minutes to insure good results. The sample should be rapidly transferred to the quenching medium to prevent undue oxidation and decrease in temperature.

*Quenching Mediums.* Kerosene, fish oil, wool oil with a mineral oil base, warm water, salt water, soapy water, a layer of oil on water. The kerosene is used for high-speed tools, tungsten, etc.; fish oil or wool oil for prac-

Etched with picric acid, x 100. Fig. 6, annealed; 7, quenched; 8, quenched and drawn at 1000 deg. C.; 9, quenched and drawn at 1000 deg. C.; 10, quenched and drawn at 1200 deg. C.; 11, raw stock. Fig. 12—Seam in Tubing, x 100. Fig. 13—Carbonized Area in Tubing; x 100.

tically all steels where toughness and hardness are needed; warm water for high carbon tools to prevent cracking; salt water to give extra hardness; soapy water for a less rigid quench than warm water; and oil on water to ease the rigid quench of the water.

*Drawing.* Heat the specimen slowly to the required temperature, hold for 30 minutes, varying time according to the size, shape, etc., of specimen; then remove and cool in still air. Do not lay on cold steel as there will be inequality of cooling.

*Oil Furnaces.* In most cases the time should be lengthened for holding the pieces to be heat-treated over that of the small electric furnaces. When the parts are inclosed in boxes it should take at least three to five hours to get the necessary results. The size of the material varies the time for holding, i.e., a small part takes less time than a large part. By careful manipulation a neutral and slightly reducing atmosphere can be maintained. Do not use too great excess air and keep the furnace doors closed as much as possible.

*Gas Furnaces.* Gas furnaces give excellent results for heat-treating. They are easy to adjust, and atmospheric conditions can be held either oxidizing or reducing which is a very important item. Every furnace should be cleaned out regularly. Oxide and other debris soon obstruct the flow of the heat and cause unequal heating; also in the case of gas, back-firing may result. In lighting a gas furnace open the door for a short time before tossing in a lighted piece of paper, then turn on the gas. Do not stand in front of the door when lighting.

*Pyrometers.* All heat-treating devices should be equipped with pyrometers. These must be checked regularly either by means of a standard pyrometer or constant melting-point materials. Care should be exercised in the method of placing the couple in the furnace or bath, for sometimes the heat registered is not the same as the heat at the point where the material is being heated. All couples should be inclosed in protecting tubes as they soon oxidize otherwise. The cold ends should be noticed to see that they are not unduly heated by the furnace. A good quick check on a pyrometer is to insert the couple in a molten bath of sodium chloride and plot the cooling curve.

LOW CARBON STEEL

Low carbon steel is used for tubing, sheet steel, armorizing, nuts and bolts.

*Tubing.* There are two kinds of tubing used, seamless and welded. It has an average chemical analysis of 0.15 per cent carbon, 0.35 manganese, 0.045 sulphur, 0.014 phosphorus; and the following physical properties when quenched at 1625-1650 deg. in oil and drawn at 1000 degrees:

|                        |                   |
|------------------------|-------------------|
| Ultimate strength..... | Pounds per sq.in. |
| Yield point.....       | 65,000            |
| Elongation.....        | 59,500            |

Tubing is oxidized very much on being heat-treated at this can be reduced to a minimum by placing the tubing in containers (larger tubing) and excluding the air; then using speed in transferring to the quenching medium. The temperature for normalizing this steel about 1650 degrees.

To determine whether the tubing is welded or seamless, a section about 1½ inches long is ground smooth

on each end and placed in a 20 per cent solution of H<sub>2</sub>SO<sub>4</sub> at a temperature of 150 deg. for 25 minutes. If welded it will show even without a microscope.

Defects often found in tubing are decarbonized spots or variations in carbon content from one end of a tube to the other, slag inclusions, seams, laps, etc. Fig. 12 shows a seam, the boundaries of which are decarbonized.

*Sheet Steel* has a composition of about 0.25 per cent carbon, 0.50 manganese, 0.045 phosphorus, 0.045 sulphur, and gives the following properties when quenched at 1600 deg. in oil and drawn at 1250 degrees:

|                        |                       |
|------------------------|-----------------------|
| Ultimate strength..... | 70,500 lb. per sq.in. |
| Yield point.....       | 60,250 lb. per sq.in. |
| Elongation.....        | 30 per cent.          |

Raw stock drawn at 1000 degrees:

|                        |                       |
|------------------------|-----------------------|
| Ultimate strength..... | 67,400 lb. per sq.in. |
| Yield point.....       | 59,700 lb. per sq.in. |
| Elongation.....        | 20 per cent.          |

The temperature for normalizing is 1575 to 1600 degrees.

Defects most often found are slag inclusions and laminated material. This laminated steel is caused from

PLATE 1.—PROPERTIES OF LOW CARBON STEEL

cold rolling below the critical range, or sometimes by phosphorus which has expelled the carbon in slow cooling. It can be improved by long annealing at about 1650 deg. but hardly ever completely removed. Phosphorus occurs in solid solution in the ferrite. In crystallizing out, the phosphorus is maximum at the surface of each crystal. These crystals on being rolled form elongated masses or bands.

Tubing and sheet steel are made into many different parts. They should be annealed first or else there is danger of cracking and strains. After the material has been fabricated it is heat-treated by quenching in oil at about 1600-1625 deg. and drawing at from 900 deg. to 1100 deg., according to the strength wanted

FIGS. 14-25

Fig. 14—Section of ear No. 1 at fracture; x 100. Fig. 15—Same some distance from fracture; x 100. Fig. 16—Section of ear No. 2 at fracture. The structure some distance away was same as Fig. 15. Fig. 17—Section from ear No. 3 at fracture; x 100. Fig. 18—Same some distance from fracture; x 100. Fig. 19—Section of ear No. 1 after annealing; x 100. Fig. 20—x 100. Fig. 21—x 100. Fig. 22—General structure of the rim; x 100. Fig. 23—The same; x 400. Fig. 24—The weld; x 100. Fig. 25—The same; x 400.

In some cases normalizing is sufficient, that is, heating to 1575 deg. to 1625 deg. and then cooling in air.

In cleaning this material it is sometimes subjected to a pickling operation (immersing in dilute acid). Care should be exercised to prevent excessive action as the weakening effect is great. Much of this type stock is brazed or welded. Acids should not be used as flux and the steel should be in the annealed condition before the weld or braze is made. In heating, if the acetylene torch is used, a sufficient area should be heated to prevent cracks from expansion and contraction.

One case was found where aluminium had been used as a deoxidizer in the manufacture of the steel. It ( $Al_2O_3$ ) had segregated in a line of dots and on brazing, being a line of weakness, caused the failure of the steel.

**Carbonizing Steel** has an average analysis of 0.20 per cent carbon, 0.50 manganese, 0.06 sulphur, 0.045 phosphorus. When quenched at 1625 deg. and drawn at 900 deg. it has the following properties:

|                           |                        |
|---------------------------|------------------------|
| Ultimate tensile strength | 70,000 lb. per sq. in. |
| Yield point               | 51,000 lb. per sq. in. |
| Elongation                | 34 per cent.           |
| Reduction                 | 70 per cent.           |

In carbonizing, the part is left in the compound from six to twelve hours, according to the thickness of the case wanted, at a temperature of 1600 deg. to 1625 deg., then cooled in the boxes to room temperature.

This material is now quenched in oil from a temperature of 1600 deg. to 1625 deg., which gives a good tough core. A second quench is given at 1450 deg. to 1475 deg. in water, after which it is drawn at about 450 deg. to relieve any existing strains.

One lot of steel used for cam shafts because of open structure became brittle and showed tiny cracks after carbonizing. In order to get away from this condition the steel was first heat-treated and then carbonized.

It is not good practice to quench material direct from the boxes in water as the resulting structure is very coarse and brittle.

**In Nuts, Bolts and Screws** the phosphorus and sulphur sometimes run high, 0.10 per cent, in which case the nuts are brittle; also they show laminations. Nuts from this material can be improved by drawing at from 1000 deg. to 1150 deg. It is not advisable to use a high-sulphur high-phosphorus material, especially where they are under stress, as they are likely to fail suddenly, due to segregation of crystals. Of course, it makes a nut or a bolt that is very easy to machine and it will oft-times pass the physical tests without a special treatment, but it absolutely should not be used in this kind of work. The usual physical test is to compress the nuts 20 per cent of the shortest diameter of the nut.

All investigations indicate that low carbon steel causes more trouble than all of the other steels. Welded tubing is sometimes mixed with unwelded necessitating the sawing off of sections and treating them in dilute acid as spoken of before. Strain lines are set up by bending tubing without proper annealing and in the case of soldering, welding, and brazing, there are numerous illustrations of the tubing being burned. Too much emphasis can not be placed on the importance of properly neutralizing any remaining solution or salt used as a flux or cleaner. A soda wash after the

operation is very good for this. It is best to use a neutral flux such as borax, if possible. Brazed joints for tubing are superior to any other when properly heat treated as shown by conclusive data in chapter on brazing and welding. It is not necessary to heat any tubing to anywhere near a burning temperature to get perfect brazes.

The use of silver solder is not necessary unless on joints between copper and brass fittings. Ordinary brazing material has been used here successfully. Two important points in regard to silver solder are its great cost and its sluggishness in use.

Sheet steel and tubing should not be sand blasted before brazing as extra heat is necessary to get the brazing material to flow. This extra heat causes rejections from burning and splitting.

Quantities of laminated sheet steel are spoiled by sending to the punch presses to be fabricated into parts before being properly annealed or normalized.

There is always considerable scale formed in heat-treating steel. This is very objectionable as it necessitates the steel being carefully cleaned; also there is considerable reduction in size.

By immersing the steel in a dilute solution of hydrochloric acid, about 6 to 10 per cent, and then treating, we get a good, clean, smooth, bright surface. This is very important as there is a large labor saving and the steel is more desirable in many ways.

Many test pieces tried out after immersing and heat treating showed the same strength as other pieces quenched or annealed at the same temperature but not subjected to acid. The decrease in diameter of the part was very slight. In the case of bar stock it was about 0.0006 inch and the surface remaining was perfectly bright. This practice is certainly worth trying especially in annealing or quenching sheet-steel where the oxide formed without the immersing in the acid solution is very objectionable.

#### STEEL TUBING INVESTIGATION

This material on being inspected showed a peculiar streak about one-half inch wide extending the entire length of the tube. A section was taken from the streak, polished, etched with picric acid and photographed at a magnification of 100.

Fig. 13 shows that the streak along the tube was a decarburized area probably caused by the tube coming in contact with some oxidizing agent (flame). This causes a line of weakness, necessitating rejection.

#### AEROPLANE FITTING INVESTIGATION

Three metal ears from certain aeroplane fittings, being fractured, are investigated to discover the source of the fracture. They were made from ordinary sheet steel. Sections from each of the ears were taken near the fracture and at the opposite side; also ear No. 1 was given a long anneal at 1650 deg. and then a section was taken. These sections were polished, etched with picric acid and photographed at a magnification of 100. The results are shown in Figs. 14 to 19 inclusive.

**Summary.** Ears 1 and 2 have a very laminated structure. The crystals were distorted by cold-working resulting in decreased ductility and increased brittleness. Strain lines would certainly be set up in bending such material, which would become enlarged by vibra-

tion. Ear 3 has a much better or softer structure than 1 and 2. It should bend easily and without the strain lines. Near the point of fracture it appears to have been bent several times before failing.

Ear No. 1, after annealing, showed as Fig. 19. This indicates that the material showing laminations as ear 1 and 2 should be given heat treatment before placing in the machine. Would suggest annealing at 1625 deg. first and then after the part is made a heat treatment of 1625 deg.; quench in oil and draw at about 100 deg. Fahrenheit.

#### INVESTIGATION OF TERNE PLATE

Terne plate showing raised spots or bubbles was investigated to see if the places were in the steel or between the steel and plating. Sections were taken, polished, etched with picric acid and photographed at a magnification of 100. Fig. 20 shows that the bubble or gas cavity was in the steel itself. There have been instances where the bubbles were under the plating and not in the steel.

#### STIRRUP INVESTIGATIONS

This stirrup (212100) showed lines on the side. These were investigated in order to determine their depth and to see if the material was distorted by any strain. Sections were taken from the place showing the lines. The sections were polished and examined and then etched with picric acid and photographed at a magnification of 100.

**Summary.** The scratches proved to be surface (die pinching) defects and had practically no depth. As shown in Fig. 21, the material is badly laminated due to rolling or excessive phosphorus. The scratches investigated are insignificant and if they are in the other parts as the one submitted will cause no damage.

The object of another stirrup investigation was to investigate the strength of the materials. The stirrups showed marks on the side that looked like cracks or strains. A part showing the marks was sectioned in two places, one showing the marks (this was heated to about 1300 deg. and straightened), and one some distance away without marks. These parts were pulled on the machines and showed as follows:

Sections heated and straightened:

A—71,500 lb. per square inch  
B—72,000 lb. per square inch

Section as the material was:

A—70,500 lb. per square inch  
B—68,500 lb. per square inch

**Summary.** This report checks out the photomicrographs in that the strength of the material is all right and the marks are surface marks only.

#### WHEEL RIM WELD

**Wheel Rim Investigation.** The object of this investigation was to contrast the structure of the steel at the weld and other places in the rim. Sections were taken, polished, etched with  $\text{HNO}_3$  solution (10 cc. in 90 cc.  $\text{C}_2\text{H}_5\text{OH}$ ) and then photographed. The results are shown in Figs. 22 to 25 inclusive.

**Summary.** The steel near the weld has its carbon content increased, probably due to the fact that a reducing flame was used in the process of welding. By a reducing flame is meant a flame with excess CO. There

should be sufficient oxygen to cause the complete reaction  $2\text{CO} + \text{O}_2 \rightarrow 2\text{CO}_2$ . A yellow flame indicates a reducing condition; but care should be taken not to confound this flame with a yellow flame caused by any soda in the air ( $\text{Na}_2\text{B}_2\text{O}_7$ ).

(To be Continued)

### Ownership of Chemical Concerns Probed by Alien Property Custodian

On the contention that the transfers of stock made just prior to the entrance of the United States into the war were not *bona fide*, the Alien Property Custodian has undertaken a searching inquiry into the ownership of Roessler & Hasslacher Chemical Co., New York; Niagara Electro-Chemical Co., Niagara Falls; and Perth Amboy Chemical Co., Perth Amboy, N. J.

According to the testimony of Wm. A. Hamann, treasurer of Roessler & Hasslacher, the stock in the three concerns was sold by Germans to American interests just before the entrance of the United States into the war because of a threatened power shortage at Niagara Falls and because of new processes being developed in this country which would be dangerously competitive.

Joseph H. Choate, conducting the inquiry for the Alien Property Custodian, questioned the good faith of the transfer and introduced a cablegram from Dr. Roessler stating that a decision could not be reached "without knowing your real intention; and whether real business or formality only is meant." The cablegram also suggested sending a "confidential man" to Germany to negotiate for the transfer of the stock, which was done last January.

The close relationship of the three firms with a group of German industrialists was shown by the testimony of Franz Roessler, vice-president of the Roessler & Hasslacher Company. His father, Friedrich Roessler was the founder of the Gold and Silver Scheide-Anstalt at Frankfort which, until the alleged transfer of stock, owned the major interest in the Roessler & Hasslacher Chemical Co., the Niagara Electro-Chemical Co., and the Perth Amboy Chemical Co. In examining Franz Roessler, it was brought out by Mr. Choate that the relationship between the owners of the German and American organizations was so intimate that the transfer of stock worth millions was made without the formality of signing papers or transferring funds.

Mr. Roessler stated that the transfer was made on the basis of \$200 a share for Roessler & Hasslacher, \$400 for Niagara Electro-Chemical, and \$200 for Perth Amboy Chemical stock. Counsel for the Alien Property Custodian pointed out that this was a low figure, considering that the Niagara Company had paid dividends as high as 1100 per cent and the other two companies as high as 100 per cent each. To this Mr. Roessler replied that the pending break between Germany and America made the German owners anxious to dispose of their stock on the best terms they could get.

The quantity of limestone sold in the Bowling Green district, Warren County, Ky., in 1917, for use in building operations, according to reported sales of four companies, decreased by 55,126 cubic feet, valued at \$12,421 from that of 1916.

4. **The Inspiration Machine.** In construction this machine is extremely simple, while in principle it shows one difference from the Callow machine, viz., that instead of splitting the pulp between a great number of

cells it is forced to travel through a series of compartments in succession. This same policy has been followed in the construction of the Minerals Separation machine.

Fig. 4 shows an Inspiration flotation machine of steel construction. The machine is divided into two compartments, A and B, each 24 feet by 8 feet 6 inches. Each compartment in turn is subdivided into eight sections, each 3 feet long. Between the compartments A and B is placed an overflow gate G which regulates the height of pulp in the minor sections of A, while the end

pan with longitudinal riffles, which riffles are cored as shown in section E-E for the interchange of air between the narrow channels thus formed. A steel spider G, Fig. 11, which forms the upper part of the porous bottom, is fastened to the lower part G' by a number of bolts around the edges. Before putting them together a porous medium (canvas) is placed between the two pieces. The air enters through a pipe P from the top which screws into the lower casting; arrangements are made, of course, to secure an air-tight joint J where the air passes through the porous medium.

FIG. 10—INSPIRATION FLOTATION ROUGHER CELL

of the second compartments is another overflow gate G' which controls the pulp-level in the sections of compartment B.

The feed enters the machine at F, passes under a baffle B and into the first section or cell C, where a froth is formed which overflows into the launders L on either side of the machine and running the entire length. The tails from this first section pass under the baffle B into the second section or cell where further froth is formed, continuing in this way through the entire length of the machine. The subdivision into two compartments is in the interest of closer regulation of the pulp-level.

In the Inspiration machine the bottom plates are all solid; all pipe connections are made from above and are at all times visible. The porous bottoms rest on top of the regular bottom of the machine and air is introduced from the top. Their construction is illustrated in Fig. 11, and consists of a shallow cast-iron

When assembled, the bars of the upper grate form channels in the lengthwise direction of the machine. These bars are the only part that protrude above the canvas, and, on account of their longitudinal arrangement, do not interfere with the passage of pulp through the machine.

**5. The Launder Machine.** This apparatus<sup>14</sup> is similar to the Callow cell, making use of air under pressure forced through canvas or some other porous medium. In this machine the air distributor is loose and is lowered from the top of the cell. With this arrangement it is evident that a distributor can be removed for repairs without interrupting the operation of the machine.

It will be seen from Fig. 12 that the machine is quite simple in construction, being merely a vat divided into six sections, the pulp flowing through a by-pass B from one cell to the other. A drop of 3 inches from

<sup>14</sup>B. M. Snider, Min. & Sci. Pr. Aug. 11, 1917.

the Central Mine, Broken Hill, Australia.

#### COMPARISON OF THE OPERATION OF THE DIFFERENT CLASSES

The object and purpose of all flotation machines in practice is to form a froth of mineral collector which, of course, is composed of air bubbles. Each bubble is loaded with mineral particles which it has picked up during its passage up through the pulp. These bubbles accumulate on the surface and are skimmed off or allowed to overflow by gravity.

In Class I, the pulp of proper consistency together with the proper amount of frothing agent passes into an agitating chamber where it is thoroughly emulsified and aerated. From this compartment it flows through an opening into a spitzkasten or settling compartment where the bubbles which have been beaten into the pulp collect mineral particles, drag them to the top to a tough and persistent froth which is skimmed off, broken up by some means, dewatered and dried as far as possible.

In Class II, 1 and 2, the pulp in an agitating compartment receives less violent mechanical agitation than in Class I. The aëration is aided by the injection of air into the pulp, thus relieving the impeller of part of its duty. Class II, 2, has a porous medium at the bottom of the settling compartment through which air is forced. This aids the bubbles formed by mechanical agitation to carry their load of mineral particles to the surface, where they are skimmed off.

In Class III the ore, water, oil and other reagents in an emulsified condition are subjected to the action of a bubble column. Air is forced through a porous medium of some kind, located at the bottom of the cell, circular or rectangular, but generally of the latter form. These bubbles are very small and proceed to pass up through the

Section A-A

FIG. 13. A CASCADE MACHINE TRIED IN AUSTRALIA

pulp one after the other. During the early part of their trip they are coated with an exceedingly thin film of oil. In this condition they are capable of collecting mineral particles (generally sulphides), which are also oiled, carrying them to the surface forming a concentrate froth.

In comparing the machines of each class it will be seen that the only real difference in mechanical frothing machines is mechanical, the underlying principle is the same. The main point of difference between the Minerals Separation machine and the Janney is in the method of driving the impeller, the latter having an individual-motor-driven impeller. Other small differences, of course, exist in mechanical details of the two machines.

Turning to the pneumatic class of flotation machine, the Callow machine differs from others in two main respects, viz., in its pulp-level control device and in its sloping bottom. A uniform pulp-level in the Callow cell is maintained by a float and plug-valve, while in nearly all other machines of this class the constant pulp-level is maintained by an overflow gate or goose neck. The sloping bottom of the Callow cell calls for some means of giving a uniform discharge of air throughout the length of the cell under a varying hydraulic head. This is accomplished by dividing the porous medium into a number of sections each having an individual valve. Other pneumatic machines have a nearly level bottom over which the hydraulic head is constant. The Callow cells also are long and quite narrow, and the feed is split to several of them, while others, excepting the launder machine, are short and wide (taking the length in the direction of the flow of the pulp).

There is a tendency in machines of late design to lower the porous bottoms from the top of the cells, and to make all adjustments in their operation from above. This is the logical place to make the adjustments since any irregularity in the operation of the machine can be noticed while the adjustment is being made. Also any cell in the series can generally be cut out without hindering the operation of the remaining ones, excepting that they are momentarily overloaded.

#### FROTHS FORMED BY MECHANICAL AND PNEUMATIC MACHINES

One thing is sure—air bubbles produce the froths in both mechanical and pneumatic systems and often the same quantities of oil are used in pulps made up with the same quantities of water. Yet the pneumatic froth dies as soon as the supply of air is cut off, while the mechanical froth does not break down for a considerable length of time—occasionally weeks. When the machines are running the froths appear very much alike, except that the froth on the pneumatic machines appears whiter and does not seem to contain as much mineral.

As far as can be learned the difference between the two froths lies largely in the different percentages of air and moisture as compared with the amount of solids. The continual supply of air by the pneumatic method produces a condition under which each rising bubble carries only a few grains of mineral, whereas in the mechanical methods the bubbles come up fairly heavily laden.

The agitation in the pneumatic method, due to the

uprising and bursting bubbles, does not afford the ideal condition to form a froth of strength. The relatively quiet spitzkasten of the mechanical machine allows the bubbles to become loaded to capacity, and this seems to toughen the froth. O. C. Ralston<sup>1</sup> states that it may rightly be called a "mineral mud." If a pneumatic machine is allowed to run for some time with no removal of froth the layer of froth on the top finally becomes similarly loaded, although the continual rush of large volumes of air through this layer keeps it more or less fluffy and wetter than a mechanical froth.

In conclusion it may be stated that the only difference in the froths produced by the two classes of machines is in the amount of water and air present for a given weight of mineral supported.

#### METALLURGICAL AND ECONOMICAL DIFFERENCES OF MECHANICAL AND PNEUMATIC MACHINES

Regarding this question Mr. O. C. Ralston makes the following statements:<sup>2</sup> "The two methods of flotation give nearly the same metallurgical results. However, comparisons made in a number of competitive tests indicate that the mechanical machines give a somewhat better extraction on coarse particles of minerals, and that the pneumatic machines make a better separation on the finer slimes—provided the oil has been well mixed with the pulp. With the same pulp the pneumatic machines give a very slightly better total extraction than the mechanical machines.

In practice the machine that gives the highest total extraction is usually considered the best. This is especially true in copper mills. In zinc mills the highest possible grade of concentrate is of importance and should be considered. Pneumatic machines require slightly less power and less labor.

#### POROUS BOTTOMS

It will be recalled that in most flotation machines canvas is the medium through which air is forced in order to give the necessary fine division. In the Flinn-Towne cell carborundum is used and is said by some not to give satisfaction on account of the clogging of the pores. Canvas may also be used in this machine.

Some experiments<sup>3</sup> with porous mediums have been made by the Inspiration engineers. Rubber sheets perforated with a multitude of needle holes have given good results; their life is quite limited, however. Sponge rubber has also been tried, but without lastingly good results. The advantage of rubber should be, in the first place, its smoothness. It would have less tendency than canvas to permit the formation of incrustations. Besides, an elastic medium should have the additional advantage of avoiding the danger of catching small sand particles in the pores of the medium.

Canvas, four ply, stitched every half inch, is considered the standard medium.

A normal capacity for a standard roughing cell of the Callow type is 50 tons per 24 hours, but varies according to the nature of the ore. At the Inspiration mill, where flotation is practiced as the prime process,

<sup>1</sup>"Answers to Questions on the Flotation of Ores," by O. C. Ralston. *Technical Paper*, 149.

<sup>2</sup>Ibid.

<sup>3</sup>"Notes on Flotation," by J. M. Callow, *Bull. A. I. M. E.* Dec. 1915. *Eng. & Min. Jour.*, Dec. 4, 1915. *Mer. Min. Jour.*, Dec. 15, 1916. *Met. & Chem. Engrg.*, Sept. 1, 1915.

each 1000-ton section employs 24 roughing cells and 4 cleaners in series, an average of 33.3 tons per roughing cell is made. At other plants a capacity of from 35 to 65 tons per cell is made.

The Inspiration standard duplex machine consists of 16 double roughing compartments 3 feet by 3 feet 4 inches and a cleaner cell of 6 double compartments 3 feet by 3 feet, treats 800 tons per day, giving a tonnage of 1.62 tons per square foot per day for a total combined area of rougher and cleaner of 492 square feet. These machines, as others, are capable of carrying a 100 per cent overload for short periods of time without much loss in the tailings.

The Kollberg and Kraut flotation machine, as recorded at the Burro Mountain Concentrator, treats 75 tons of dry feed per day per cell. The manufacturers claim for it a capacity of from 80 to 150 tons per day.

The Cole-Bergman flotation machine is designed to handle large tonnages and, according to Mr. David Cole, will handle twice that of the Callow cell for the same floor space. The three-stage machine shown in Fig. 9 will handle up to 400 tons per day.

The Flinn-Towne Cell, on account of its cylindrical shape, is not adaptable where large capacities are required. The cell shown is designed to treat 40 tons per 24 hours.

A bank of Minerals Separation machines, containing 15 agitators each, 3 feet square, and 14 spitzkastens, handles about 400 tons of sand or 175 tons of slime per day.\*

Janney mechanical machines installed in a row of from 5 to 15 cells will treat from 100 to 500 tons per row.

Janney mechanical-air cells installed in a series of one mixer and 5 flotation cells will treat 200 to 250 tons per day of 24 hours.

#### AIR AND POWER CONSUMPTION

The air consumption per square foot of the Inspiration machine is about 11.8 cubic feet per minute at a maximum pressure of 4½ pounds. The actual power consumed is 2.63 kilowatt-hour per ton of ore treated. Callow cells at the National Copper Company, using approximately 950 cubic feet of air at 4 pounds pressure, and treating 500 tons per day on 8 roughers and 2 cleaners, require 3.5 hp. per cell or 1.25 kilowatt-hour per ton.

A Minerals Separation mechanical agitation machine, with 15 agitator compartments 2 feet square and 14 spitzkastens, as installed at Anaconda, required 45 to 55 hp. under full load.

For each Janney cell about 150 cubic feet of air per minute at 4 to 5 pounds pressure is required.

The Janney mechanical cell has a 10-hp. motor installed over each, while 8 hp. is required to operate it.

The following table of power used by machines gives an interesting comparison:

| Machine                          | Kilowatt-Hours per<br>Ton of Solids |
|----------------------------------|-------------------------------------|
| Janney (with air baskets)        | 4 to 6                              |
| Minerals separation, mechanical  | 4 to 5                              |
| Minerals separation, submergence | 3.5                                 |
| Pneumatic                        | 3                                   |
| K. & K. (claim in catalogue)     | 2                                   |

These are of illustrative value only.

#### COST OF FLOTATION MACHINES

The cost of flotation machines is usually the smallest item in the cost of a plant, especially when compared with that of crushing machinery, filters, housing, etc.

The following summarized table of a number of installations has been reduced to unit figures and is of interest in comparing pneumatic and mechanical machines:

#### MECHANICAL FROTHING MACHINES

| Capacity, Tons per Day | Cost per Ton of<br>Daily Capacity |
|------------------------|-----------------------------------|
| 25                     | \$30 to \$50                      |
| 50                     | 25 to 45                          |
| 100                    | 20 to 40                          |
| 250                    | 15 to 35                          |
| 1000                   | 12 to 25                          |

#### PNEUMATIC FROTHING MACHINES

| Capacity, Tons per Day | Cost per Ton of<br>Daily Capacity |
|------------------------|-----------------------------------|
| 25                     | 25 to 40                          |
| 50                     | 12 to 20                          |
| 100                    | 8 to 12                           |
| 250                    | 6 to 8                            |
| 5000                   | 4 to 6                            |

The wide variation in these costs is due to differences in the machines used and the ores treated. The figures, however, serve to illustrate what can be expected.

Texas School of Mines,  
El Paso, Texas

#### Skilled Enlisted Men to Be Returned to Industries by the War Department

In response to appeals from all over the country, the War Department has decided upon a policy which will permit the return to necessary industries of highly skilled men taken from such industries, under a system of furlough which will be automatic, and which will not in the future as in the past leave to the discretion of company and other subordinate commanders the question of whether such furloughs shall be granted. Thousands of applications for such furloughs are now being sent out of Washington by various branches of the War Department, in response to the appeals of manufacturers and other producers of war material whose draftsmen, mechanics and other employees, engaged in the past and now upon Government orders for war work, have been taken from them by operation of the draft.

The adoption of the new policy means that enlisted men are to be returned to industry only in cases where the drafted man's employer is willing to swear that the man is badly needed and that no one can take his place. The Government department for which the manufacturer or other employer is working will, upon application, send a blank form to the employer, which he must fill out, swear to before a notary, and have signed by a government inspector who is conversant with the facts. The signed application then goes to the Adjutant General's office, with request from the interested Government department that the man wanted be granted an indefinite furlough, without pay, with the promise that after the need for the man's service has passed he will be returned to the Army and the Government notified.

While such men are on furlough they are not to be allowed to wear the uniform. The company employing such men must furnish the Government each month a report that such men are still in employment and the class of work engaged in. In case such men leave their employment, the employers must immediately notify the Government.

# Aluminium and Its Light Alloys

Light Alloys of Aluminium Just Developing as Important Materials of Construction, Especially in Motor and Aircraft Industries—Discussion of Chemical and Physical Properties of the Element

By PAUL D. MERICA\*

**P**ROBABLY no metal has experienced the rapid development of its manufacture and scope of application that aluminium has within the past 30 years. A curiosity 60 years ago, it has become almost a household and industrial necessity today, and the growth of its use and application has not yet ceased. The motor and particularly the aircraft industries, today, are demanding materials for construction that are strong and light. If the development of the use of the metal, aluminium, lies mainly in the past, that of the development of its light alloys is really just beginning, and the future conceals, without a doubt, most important discoveries concerning the properties and uses of these alloys.

During the past few years the metal and its alloys have been the subject of much investigation and study, the results of which are scattered throughout the technical literature at least of six languages and eight countries. The author has considered that a brief, comprehensive resumé of what is known about this extraordinary metal may be of value to the multitude of those who are today manufacturing, selling, buying or using it in any of its many forms, and who otherwise may not have access to the information relative to the characteristics of the metal.

The data and information have been put in the form of tables and curves; the curves have been reproduced in such dimensions that accurate interpolation of values on them is possible by the use of a rule graduated in decimal parts of a centimeter. The probable degree of accuracy of data is indicated, or implied, by the number of significant figures in the values given.

## I. COMMERCIAL ALUMINIUM.

The metal, aluminium, is produced by the electrolysis of a bath of molten bauxite and cryolite in carbon lined pots. Owing to the impurities in the materials used, the metal thus obtained is itself not pure but contains small and equal amounts of both iron and silicon.

There are two well recognized grades of ingot aluminium on the market:

Grade 1 containing 99 per cent or more aluminium.

Grade 2 containing 98 per cent to 99 per cent aluminium.

These are furnished in ingot form and in the form of slabs or billets for rolling.

The Aluminium Co. of America is the sole producer in this country of metallic aluminium; there are, however, a number of firms which manufacture the metal or its alloys.

The story of the uses and applications of aluminium

is a quite long one. As might be expected it has made a place for itself everywhere where lightness, malleability, high electrical conductivity, and moderate resistance to corrosion are service features.

About one-third of the production is consumed in the automobile industry (Richards, 39), where it is used in the form of castings and sheet for chassis and panelling. Other major uses of this metal are for cooking utensils and vessels of all kinds, for electrical conductor to replace copper and in the form of alloy castings. It is also used as a deoxidizing agent in the manufacture of iron and steel, in the Goldschmidt Thermit process, as a substitute for stone in lithographic work, as wrapping foil, as paint powder, as a constituent of the explosive ammonal, as the anode in electrolytic rectification cells; it is manufactured in every commercial form; bars, tubes, sheets, powder, foil, sections, and ingots. Richards (45) lists about 200 commercial and technical uses of aluminium.

It may be worth while to point out that aluminium may be used as a substitute in many cases for metals which are either more expensive or are difficult or impossible to obtain. During the present shortage of tin aluminium foil can be used to replace tin and tin-lead alloy foil; it can be used at least for many cases as a constituent of bronze castings to replace tin. The greater cost per pound of aluminium than metals such as lead and zinc should not be allowed to give a false impression of its cost. In many cases, such as that of foil, of small manufactured articles, and of many castings, the size and shape of the article is determined by its use, so that it is the cost per unit of volume of the material, not that per unit of weight which must be considered. Aluminium compares quite favorably in this respect with other metals as the following table indicates.

| Metal          | Cost per Unit of Weight, per Lb. | Cost per Unit of Volume, per Cu.In. |
|----------------|----------------------------------|-------------------------------------|
| Copper.....    | 15c.                             | 4.8c.                               |
| Tin.....       | 38c.                             | 10.0c.                              |
| Lead.....      | 4c.                              | 1.6c.                               |
| Zinc.....      | 91c.                             | 1.4c.                               |
| Aluminium..... | 23c.                             | 2.2c.                               |

## II. METALLOGRAPHY OF ALUMINIUM.

Aluminium undergoes no thermal or other transformation in the solid state. Its microstructure is quite simple; the metal consists of grains or crystals within which are formed "rests" of the iron-aluminium compound, FeAl<sub>3</sub>, and of silicon. The microstructure is shown in figures 1 to 4. These impurities undoubtedly have a considerable effect on the properties of the metal and even on those of its light alloys.

## III. CHEMICAL PROPERTIES.

Aluminium is a very active element and under proper conditions reacts readily with other elements and substances such as chlorine, sulphur, oxygen. Its molecu-

\*Bureau of Standards; a more comprehensive treatment of this subject will be given in a forthcoming circular of the Bureau of Standards. Numbers in parenthesis following authors' names refer to a bibliography which will be published at the end of this series of articles.

lar heat of combustion is ( $\text{Al}_2\text{O}_3 = 102.2$  grams) 392,600 calories.

The ease, however, with which aluminium reacts with oxygen, water, etc., is very dependent upon the physical state of the metal. As a powder or in an amalgam for example it reacts quite readily with air, water and other substances as one would expect from its high heat of reaction. As a solid mass, however, its rate of reaction with the same substances is very much slower, often almost unnoticeable; this in many cases, as for example its behavior towards oxidation, is undoubtedly due to its protection by a thin coating of reaction product, be it oxide, hydrate or otherwise. An important corollary of this fact is that the rate of corrosion of aluminium and of its light alloys depends on whether this protective coating of oxide once formed remains in place, protecting the remainder of the metal, or whether it is removed as it is formed. Thus the corrosion of the metal and its alloys is much more rapid in running water, and under conditions in which air and water erosion also play a part than in still water.

Aluminium in the solid form is corroded slowly and superficially only by pure water. In the air, damp or dry, it is also only superficially oxidized. When heated to  $400^\circ\text{C}$ . for 10 minutes in air a beginning oxidation is noticed which increases slowly up to  $800^\circ\text{C}$ . and then increases rapidly. Very finely divided aluminium, wire or foil, will decompose water very slowly but noticeably at  $100^\circ\text{C}$ .

Ammonium hydroxide attacks aluminium slowly, forming aluminium hydrate; sodium and potassium hydroxides ( $\text{NaOH}$  and  $\text{KOH}$ ) attack it quite rapidly.

Sulphur, free or dissolved in carbon disulphide ( $\text{CS}_2$ ), does not affect aluminium at ordinary temperatures.

A solution of mercury salt attacks aluminium, the mercury liberated by the reduction of the salt amalgamates the aluminium. The aluminium in this amalgam is very active and from it aluminium oxide is very rapidly formed by the action of water. Aluminium articles must therefore be protected from the action of mercury salts.

Cold concentrated or dilute nitric acid ( $\text{HNO}_3$ ) attacks aluminium only very slowly; the metal becomes "passive" under the action of this acid. Dilute and concentrated sulphuric acid ( $\text{H}_2\text{SO}_4$ ) attack aluminium but slowly when cold. When concentrated sulphuric acid is heated with aluminium the latter is attacked with formation of sulphur dioxide ( $\text{SO}_2$ ). Dilute and concentrated hydrochloric acid ( $\text{HCl}$ ) readily dissolve aluminium, as well as other mineral acids in the presence of metal chlorides.

Seligman and Williams (99, 100, 102) have carried out extensive tests of the resistance of aluminium to corrosion by acids, particularly nitric, sulphuric and acetic acids, the results of which are of the greatest practical value in view of the extensive use of aluminium for kitchen utensils and for acid vats and condensers. Their conclusions follow:

The rate of attack of aluminium by cold acetic acid is small; it increases with increasing dilution of the acid. Aluminium vessels can be used for containing concentrated nitric acid, when cold; with hot nitric acid of any concentration aluminium has but a limited life. Dilute, cold nitric acid also can be handled in aluminium vessels,

but the life of the latter is not as long as with the concentrated acid.

The corrosion of aluminium is greater in mixed sulphuric and nitric acids than in either alone (contrary to previously held opinion), and aluminium vessels should be used only with caution for handling such mixed acids.

The presence of impurities, iron, silicon and copper is of little influence on the corrosion in acids; the presence of copper is much more injurious when the corrosion is by dilute acids than when by concentrated acids.

## 1. CORROSION

Our detailed knowledge of the corrosion of aluminium is perhaps largely due to Heyn and Bauer (130) who in a very thorough investigation described the characteristic variations in the behavior of aluminium to corrosion in water or air and studied the effect of different conditions upon this corrosion. Their investigation was made following an extensive epidemic of disintegration of aluminium cooking utensils which were then being put on the market. Upon storing, many of these became exfoliated, cracked and blistered, undergoing in many cases an almost complete disintegration.

Heyn and Bauer found that aluminium undergoes two types of corrosion; it may corrode uniformly, a coating of oxide being formed over the whole surface, or it may be attacked locally, with formation of blisters and exfoliation. The latter type of corrosion is of course most dangerous and destructive; it appears to occur only when the aluminium is in the hard or cold worked condition and with certain types of tap water or salt solutions. Calcium salts seem to be accelerators of this type of corrosion. Tap water for example produces only slight uniform corrosion after several months on soft or annealed sheet; whereas it causes local corrosion, blistering and disintegration with hard sheet. Distilled water and many other salt solutions on the other hand will not cause blistering even with hard sheet. Heyn and Bauer suggest that cooking utensils might well be annealed in order to eliminate entirely the danger of local corrosion.

This distinctive type of local corrosion is probably due (1) to the presence of initial stresses in the hard sheet which cause strains and buckling when released by corrosion and (2) the fact that as Heyn has shown "hard" aluminium is electropositive to soft or annealed aluminium (by about 0.03 volts in tap water).

An idea of the extent of corrosion undergone by aluminium may be gained from the following tables taken from Heyn and Bauer's results:

In distilled water, with access of air, the diminution in thickness of the sheets (from 0.8 to 1.2 mm. thick) in 207 days was:

|                         |            |
|-------------------------|------------|
| for "hard" sheet.....   | 0.0045 mm. |
| for "medium" sheet..... | 0.0048 mm. |
| for "soft" sheet.....   | 0.0054 mm. |

Samples of "medium hard" sheets showed the following losses in weight after 61 days in sodium chloride ( $\text{NaCl}$ ) solution of the following concentrations:

|        |      |           |
|--------|------|-----------|
| 0.34/N | NaCl | .0015 mm. |
| 0.86/N | NaCl | .0024 mm. |
| 3.42/N | NaCl | .0029 mm. |

No effect of varying silicon content of the aluminium within the range 0.57 per cent to 0.86 per cent of silicon

was noticed upon the type or amount of corrosion. It is not attacked by water in the absence of air or oxygen.

The corrosion is much increased as the temperature rises. For example, a sample of medium hard sheet

The Aluminum Company of America (12) states that aluminium "withstands the action of sea water better than iron, steel or copper. Strips of aluminium placed upon the sides of a wooden vessel were found

FIG. 1—NINETY-NINE PER CENT ALUMINIUM INGOT; ETCHED WITH 0.10% NaOH; x 100  
FIG. 3—HARD-ROLLED ALUMINIUM SHEET (ANDERSON, 96); ETCHED WITH HF; x 100

FIG. 2—ALUMINIUM INGOT; ETCHED WITH 0.10% NaOH; x 1000  
FIG. 4—ANNEALED ALUMINIUM SHEET (ANDERSON, 96); ETCHED WITH HF; x 50

showed the following decrease in thickness after 48 days in tap water:

|           |            |
|-----------|------------|
| at 20° C. | .00039 mm. |
| at 70° C. | .0011 mm.  |

Bailey (121) finds that the presence of copper and sodium in it increases the corrosion of aluminium, and that in general the greater the purity of the metal the less the corrosion.

Guillet (123) finds that soda solutions attack aluminium and its alloys very rapidly. A sample of aluminium which lost only 2 mg. weight after 8 weeks in Seine water lost 3.95 grams after the same time in a 1 per cent soda solution. Alloys containing copper are much more readily attacked than pure aluminium and he corroborates Heyn's claim that in general cold worked or hard aluminium resists attack less than the soft or annealed metal.

to be corroded less than .005 in. after 6 months exposure to sea water. Copper sheet treated similarly was corroded nearly twice as much."

2. PROTECTION OF ALUMINIUM AGAINST CORROSION

Both aluminium and its alloys are attacked by sea or salt water; the alloys of aluminium are attacked also by fresh water in which aluminium is much more stable. In order therefore to be able to utilize these alloys for construction purposes some method of protection against corrosion must be sought.

Of particular significance is the question of the protection of such alloys against corrosion in aircraft construction. Frames, beams and struts for rigid dirigible construction have already been made entirely from aluminium alloys and it is quite possible that similar construction will be tried for aeroplane construction to

replace parts now fabricated of wood, since there is now no doubt of the mechanical superiority of the alloy, duralumin, weight for weight, to wood or steel. An objection often raised against the use of these alloys is that they will corrode when exposed to the weather for any length of time.

Although it is impossible to electroplate aluminium, the effectiveness of such a coating is highly questionable. The coatings on aluminium do not adhere satisfactorily, and the metals used are all electronegative to the aluminium, such that if the coating were once punctured the corrosion at that point would be to a great degree accelerated.

The use of a paint, varnish or enamel seems the most promising solution of the problem. Some experiments carried out by Sabin in 1896 (135) will indicate how far the protection of aluminium by such means is possible today.

Sabin carried out two series of tests using in the first series 30 plates of aluminium and aluminium alloy and 25 plates in the second set. These were coated with various paints, enamels, and varnishes, suspended in cages: (1) in the first series, from 5 to 6 ft. below the water level in New York Navy Yard for 6 months; (2) in the second series, for 2 years in the water of the Norfolk Navy Yard, and about 13 months in the New York Navy Yard. The first series of tests showed that several coatings, namely, "Sabin process" pipe-coating enamel, baked; "Durable metal coating," both baked and unbaked; chromium oxide in Kauri resin oil-varnish, unbaked; Spar varnish, baked and unbaked; white zinc in Kauri resin oil-varnish, gave practically perfect protection to the 5 alloy series. In many cases blisters had formed in the coating, but no corrosion had set in. The same plates were again immersed in the water at the New York Navy Yard in 1897 for about 13 months; some of them were lost, but those which were not were recovered and upon examination were found to be still uncorroded.

The same may in general be said about the results of the second series of tests, although some of the coatings, notably those made with oil alone as a vehicle were destroyed by this exposure. Many remained absolutely intact, while during the same time heavy iron supporting chains were completely rusted away. The general conclusion from these tests is that aluminium and its alloys can be efficiently protected against corrosion under most severe conditions by the use of an enamel or varnish paint (the oil paints proved very inferior in these tests), and this fact, the result of extensive tests, is recommended to the attention of the aeronautical engineer for his investigation.

#### IV. PHYSICAL PROPERTIES

There are given below the best values available for the most common physical properties of commercial purest aluminium:

The density of annealed aluminium is 2.702; that of cold worked metal, 2.70.

The electrical resistivity is 2.828 microhm cm.; this corresponds to 60.3 per cent of the electrical conductivity of annealed copper (International Standard).

The temperature coefficient of electrical resistivity at 20 deg. is .0039.

The thermo-electromotive force of aluminium to copper (Northrup, 156) is given by the formula

$$10^6 E = 4.51 t - 0.0122 t^2 + 0.0000433 t^3.$$

The electrolytic solution potential of aluminium to a normal solution of its normal salts with sulphuric, hydrochloric and nitric acids respectively is +1.040, +1.015 and +0.775 volts (Neumann, 160).

The magnetic susceptibility of aluminium is  $+0.65 \times 10^6$  (Honda, 161).

Aluminium melts at 658.7° (Bureau of Standards, 163), and boils, under atmospheric pressure, at about 1800°C. (Greenwood, 164).

The heat of fusion of aluminium is approximately 64 cal. per gram (Laschtscheno, 98).

The thermal conductivity of aluminium at 18° C is .504 cal. per 1 deg. C., per second, per cubic centimeter (Lees, 166).

The thermal expansivity of aluminium may be represented by the following equation (Bureau of Standards):

$$\frac{\Delta l}{l_0} \text{ (between 0 deg. and 300 deg. C.)} = (22.3 t + .011 t^2) 10^{-6}.$$

The specific heat of aluminium at 18°C. is .2143 cal. per gram, degree C. (Jaeger and Dieselhorst, 153). It may be represented between 0° and 100°C. by the equation

$$s = .2124 + .000104 t.$$

The total heat required to heat aluminium from 0°C. to its melting point is 187 cal. per gr. (Latschenko, 98).

The optical reflecting power of aluminium for  $\lambda$  is .583  $\mu$  is 83 per cent (Drude, 181).

#### V. MECHANICAL PROPERTIES.

*Elasticity.* The best values for E, the (Young's) modulus for elasticity are given by Brislee (183) for 99.3 per cent aluminium bars and wire. This mean value is

$$E = 9,810,000 \text{ lb./sq. in at } 17^\circ\text{C.}$$

$$\text{for bars, } E = 9,840,000 \text{ lb./sq. in.}$$

$$\text{for wire, } E = 9,790,000 \text{ lb./sq. in.}$$

Koch and Dannecker (182) gives the following values for the modulus (F) of torsion ( $E = (\text{aprox.}) 2.72 F$ ) at higher temperatures:

| Temperature, °C. | Modulus of Torsion,<br>Lb. per 1 Sq.In. |
|------------------|-----------------------------------------|
| 20 .....         | 3,870,000                               |
| 100 .....        | 3,730,000                               |
| 200 .....        | 3,450,000                               |
| 300 .....        | 3,100,000                               |
| 400 .....        | 2,630,000                               |
| 450 .....        | 2,030,000                               |
| 500 .....        | 680,000                                 |

Poisson's ratio ( $\mu$ ) is given by Cardani (185) as .363, by Schaefer as .359. A mean value of .36 may be accepted. (Katzenelsohn finds that  $\mu$  increases 15.7% between 0° and 100°C.

*Tensile Test.* Aluminium may best be "normalized" by mechanical working (rolling, drawing, forging) followed by annealing at about 400°C. In this, soft state it possesses the following mean tensile properties:

|                                              |
|----------------------------------------------|
| Tensile strength 12,500 to 15,000 lb./sq. in |
| 8.78 to 10.54 kg./sq. mm.                    |
| Yield point 8000 to 9000 lb./sq. in.         |
| 5.52 to 6.32 kg./sq. mm.                     |
| Elongation in 2 in. .... 10–40%              |
| Reduction of area. .... 20–30%               |

The following table (No. 1) will give an idea of the tensile properties of this metal in other forms.

TABLE I—TENSILE PROPERTIES OF ALUMINIUM (1)

| Form        | Tensile Strength | Tensile Test Yield Point | Elongation in 2 In. | Reduction of Area |
|-------------|------------------|--------------------------|---------------------|-------------------|
| Sand cast   | 11,000-13,000    | 8,500                    | 15-25               | ...               |
| Chill cast  | 12,000-14,000    | 9,000                    | 15-25               | ...               |
| Sheet:      |                  |                          |                     |                   |
| Annealed    | 12,000-15,000    | 8,000-9,000              | 12-35               | 20-30             |
| Half-hard   | 18,000-22,000    | 9,000-12,000             | 5-12                | 20-30             |
| Hard        | 22,000-35,000    | 12,000-25,000            | 1-7                 | 20-30             |
| 12 gage     | 25,000           | ...                      | 7                   | ...               |
| 16 gage     | 28,000           | ...                      | 5                   | ...               |
| 20 gage     | 30,000           | ...                      | 3                   | ...               |
| Bars (hard) | 28,000-35,000    | 14,000-23,000            | ...                 | 30-40             |
| Wire (hard) | 25,000-55,000    | 16,000-33,000            | ...                 | 40-60             |
| 40 mil      | 31,000           | ...                      | ...                 | ...               |
| 80 mil      | 28,000           | ...                      | ...                 | ...               |
| 120 mil     | 25,000           | ...                      | ...                 | ...               |
| 200 mil     | 22,000           | ...                      | ...                 | ...               |

(1) These figures are by the Aluminum Co. of America (12), and others.

Gavey (196) has found that the duration of application of stress has a marked effect on the ultimate tensile stress. Hard drawn aluminium wires which had been in service as electrical conductors for a few months and had become somewhat corroded showed the following ultimate tensile stress:

| Time of Application of Ultimate Breaking Load | Breaking Load, Lb. | Tensile Stress (1), Lb. Sq. In. |
|-----------------------------------------------|--------------------|---------------------------------|
| Ordinary tensile test                         | 325                | 25,300                          |
| 1 hour                                        | 300                | 23,300                          |
| 2 hours                                       | 280                | 21,800                          |
| 118 hours                                     | 240                | 18,700                          |
| 525 hours                                     | 220                | 17,100                          |
| 1,900 hours                                   | ...                | Not broken but still stretching |

(1) Wire weighed 75 lb. per mile—was, therefore, apparently No. 10 British wire gage—values in column 3 calculated on this basis.

**Compression test.** The behavior of aluminium in compression is described by the Aluminum Co. of America (12) as follows:

Elastic limit (1) ..... 6000-25,000 lb./sq. in.

Ultimate strength (1) 16,000-100,000 lb./sq. in.

Elmendorf (189) finds an average value (11 tests) of 67,000 lb./sq. in. for the ultimate strength of cast aluminium.

**Hardness.** The selerescope hardness (magnifying hammer) of annealed or of cast aluminium varies from 4 to 6. The hardness of cold-rolled sheets is increased to from 13 to 15; the Brinell hardness (500 kg., 10 mm. ball, 30 seconds) of cast aluminium varies from 23 to 28.

**Ductility (Erichsen test).** The ductility of soft annealed aluminium sheets, such as are used for stamping and drawing is well indicated by the Erichsen test. Average Erichsen values (187, 188) are given below for different gages of commercial aluminium sheets:

| B.&S. Gage | Thickness in In. | Erichsen Value |
|------------|------------------|----------------|
| 28         | 0.0126           | 5.5-7.5        |
| 26         | 0.0159           | 7.0-8.0        |
| 24         | 0.0201           | 7.0-8.5        |
| 22         | 0.0253           | 7.0-8.5        |
| 20         | 0.0319           | 7.5-9.0        |
| 18         | 0.0403           | 8.0-9.5        |
| 16         | 0.0508           | 9.0-10.5       |
| 14         | 0.0640           | 10.0-11.5      |
| 12         | 0.0808           | 10.5-12.0      |
| 10         | 0.1018           | 11.0-12.5      |

**Alternating stress test.** The only tests of which results are published are those on the White-Souther machine by Elmendorf (189), on cast aluminium of tensile strength averaging 15000 lb./sq. in. He finds the following relation:

$$S = 48,000 R^{-0.113}$$

$$S = \text{fiber stress}$$

$$R = \text{No. of reversals to rupture.}$$

This gives for 10,000 lb./sq. in. fiber stress, one million reversals, for 7800 lb./sq. in., ten million reversals.

## MISCELLANEOUS

**Density.** Seven samples of hard drawn wire of from 99.52 to 99.60 per cent aluminium, tested at this Bureau

| 200                       | 20,800                            | 15,800                                          | 22.2                    | 41                   |
| 300                       | 10,100                            | 10,100                                          | 31.4                    | 35                   |

TABLE IV—TENSILE TESTS OF ALUMINIUM BARS AT HIGHER TEMPERATURES (1) (BAUMANN 201)

| Temperature, °C. | Tensile Strength, Lb. per Sq. In. | Elongation in 2.7 Cm. (1.97 In.) | Reduction of Area |
|------------------|-----------------------------------|----------------------------------|-------------------|
| 20               | 14,000                            | 43.3                             | 64.5              |
| 60               | 12,600                            | 49.9                             | 71.9              |
| 100              | 9,860                             | 66.8                             | 76.6              |
| 200              | 5,980                             | 78.1                             | 87.2              |
| 300              | 3,360                             | 79.8                             | 92.8              |
|                  | Not Annealed                      |                                  |                   |
| 20               | 19,900                            | 16.3                             | 43.7              |
| 100              | 13,700                            | 35.8                             | 66.0              |
| 200              | 9,230                             | 44.7                             | 76.9              |
| 300              | 4,270                             | 59.9                             | 83.7              |

(1) These tests were made on 99% aluminium bars 17, 12, 8 and 4 mm. thick. The values given are averages of the results for the bars of the 4 thicknesses.

TABLE V—EFFECT OF TEMPERATURE ON THE TENSILE PROPERTIES OF ALUMINIUM (BENGOUGH, 200). (THE METAL TESTED CONTAINED 99.56% AL)

| Temperature of Test, °C. | Tensile Strength, Lb. per Sq. In. | Tensile Properties Yield Point, Lb. per Sq. In. | Elongation in 2 In. % | Reduction of Area, % |
|--------------------------|-----------------------------------|-------------------------------------------------|-----------------------|----------------------|
| 20                       | 19,200                            | 12                                              | 75                    | 75                   |
| 200                      | 14,100                            | 15                                              | 78                    | 78                   |
| 275                      | 11,110                            | 17.2                                            | 79                    | 88                   |
| 330                      | 7,600                             | 20.3                                            | 88                    | 88                   |
| 375                      | 3,800                             | 25                                              | 90                    | 96                   |
| 396                      | 2,150                             | 65                                              | 96                    | 96                   |
| 520                      | 900                               | 88.5                                            | 96                    | 96                   |
| 565                      | 540                               | 70.3                                            | 96                    | 96                   |
| 610                      | 660                               | 75.0                                            | 96                    | 96                   |
| 625                      | 420                               | 39.0                                            | 96                    | 96                   |

averaged 2.6991 in density, ranging from 2.6983 to 2.6996 (151). Brislee (143, 144) has shown that the density of aluminium depends upon the heat treatment

FIG. 7—TOTAL HEAT IN ALUMINIUM BETWEEN 2°C. AND 24°C. (LASCHITSCHENKO)

and amount of mechanical working it has suffered. He found that the mean increase of 7 samples of density of cold worked metal upon annealing was 0.0017 or 0.063 per cent. Annealed aluminium may be regarded as having a density of 2.702, cold worked or hard aluminium one of 2.700.

#### VI. PHYSICAL PROPERTIES AT HIGHER AND LOWER TEMPERATURES.

Niccolai (205) has determined the specific electrical resistivity of aluminium at temperatures from  $-180^{\circ}\text{C}$ .

FIG. 8—EFFECT OF TEMPERATURE ON TENSILE PROPERTIES OF ALUMINIUM (BAUMANN) (BENGOUGH)

to  $400^{\circ}\text{C}$ . His values are given in Table 2 and plotted in Fig. 5. Lees (166) also gives similar values for the electrical resistivity at lower temperatures.

The effect of low temperatures upon the atomic heat of aluminium is shown in the Fig. 6 from data by Nernst (202).

The total heat of aluminium at higher temperatures has been measured by Laschtschenko (98) from  $t^{\circ}$  to  $24^{\circ}\text{C}$ . His results are plotted in Fig. 7.

Lees (166) gives the following values for the thermal conductivity of 99 per cent aluminium.

| Temperature in $^{\circ}\text{C}$ . | Thermal Conductivity in Cal. per Sec.—per $\text{Cm}^2$ —per $1^{\circ}\text{C}$ . |
|-------------------------------------|------------------------------------------------------------------------------------|
| -170                                | 0.524                                                                              |
| -160                                | 0.514                                                                              |
| -150                                | 0.508                                                                              |
| -125                                | 0.491                                                                              |
| -100                                | 0.492                                                                              |
| -75                                 | 0.493                                                                              |
| -50                                 | 0.496                                                                              |
| -25                                 | 0.499                                                                              |
| 0                                   | 0.502                                                                              |
| +18                                 | 0.504                                                                              |

Investigation has been made by Breuil (204), Baumann (201), and Bengough (200), of the effect of temperature on the tensile properties of aluminium. Their results are shown in the Tables 3, 4 and 5, and in Fig. 8. The variation in the results is due in all probability to the difference in the speed of testing which has undoubtedly much effect on the results obtained.

(To be Continued)

### Asphalt and Petroleum Residues in 1917

Statistics just completed under the supervision of J. D. Northrop of the U. S. Geological Survey show a marked decrease in the production of maltha, gilsonite, elaterite and grahamite, bituminous rock, and ozokerite—\$0,904 tons valued at \$735,924 being produced, which is 17,570 tons less than in 1916.

The quantity of manufactured asphalt (including road oils and flux) produced in 1917 from petroleum of domestic origin increased about 2 per cent compared with 1916, and the quantity of corresponding material manufactured in this country from Mexican petroleum increased about 13 per cent, as a consequence of which the net gain over the production in 1916 was nearly 7 per cent.

The total sales in 1917 of manufactured asphalt derived from domestic petroleum amounted to 701,809 short tons, valued at \$7,734,691. This total includes 327,142 tons, valued at \$4,011,980, of solid and semisolid products used in the paving and roofing industries, and 374,667 tons, valued at \$3,722,711, of liquid products, including road oils, flux, and asphaltic paints.

California maintained its supremacy in the production of oil asphalt. Its output from 14 petroleum refineries in 1917 aggregated 220,294 tons, valued at \$2,100,252, and included 135,160 tons of solid and semisolid products, valued at \$1,486,609, and 85,134 tons of liquid products, valued at \$613,643. Refiners handling oil from the Oklahoma-Kansas field produced 206,223 tons of oil asphalt, valued at \$1,975,493, including 73,410 tons of solid and semisolid products, valued at \$747,651, and 132,813 tons of liquid products, valued at \$1,227,842.

The total sales in 1917 of manufactured asphalt derived from Mexican petroleum amounted to 645,613 short tons, valued at \$7,441,813, and included 338,485 tons of solid and semisolid products, valued at \$4,657,152, and 307,128 tons of liquid products, valued at \$2,784,661.

The imports of native asphalt, oil asphalt, and bituminous rock for consumption in the United States in 1917 aggregated 187,886 short tons, valued at \$993,115, a gain in quantity of 40,173 tons, or 28 per cent, over 1916. The exports of unmanufactured asphalt in 1917 amounted to 30,107 short tons, valued at \$587,256, a loss of 10,709 tons, or 35 per cent, compared with 1916. In addition asphalt products to the value of \$585,472 were exported in 1917.

## The Deresination of Rubber

### A Resume of the Art of Improving Low-Grade Rubber by Removal of Resin—Outline of Processes Proposed—Deresination of Guayule May be Resumed in a Short Time

BY ANDREW H. KING

IN PREVIOUS papers the writer has pointed out that rubber may be represented by the chemical formula  $2(C_{10}H_{16})_n$ . The subscript  $n$  denotes the degree of polymerization on which depends, to a great extent, the value of the rubber, i.e., whether it is high- or low-grade.  $C_{10}H_{16}$  is the basic formula for the whole terpene series to which rubber is very closely related, if not actually a member, as was held by Weber. Many organic compounds, the terpenes in particular, possess the property of becoming resinified by oxidation in the air or under the influence of chemical reagents. In other words, they may be converted to substances very similar to the resins which occur in nature. The natural resins are solid, amorphous, and generally brittle masses which break with a conchoidal fracture. They are insoluble in water and acids, but soluble in acetone, alcohol, ether, turpentine, etc. They are found in the solid form in abundance and occur also as balsams; that is, dissolved in terpenes or etherial oils from which they can be separated by steam distillation. Resins dissolve in alkalies to form resin soaps but are precipitated when the solution is acidified. Most resins consist of a mixture of somewhat complicated acids, the so-called resin acids.

The resins of rubber are extremely complex and are but very imperfectly understood. Neither their origin nor their composition are definitely known. The only way in which they can yet be safely defined is that they are substances which may be extracted from crude rubber by acetone or alcohol, and contain varying amounts of oxygen.

In regard to the relation of resins to rubber, only three views are possible:

- (1) They are derivatives of rubber, oxidation products, etc.
- (2) They are terpene bodies of low polymerization.
- (3) They were produced by the plant at the time of the formation of rubber but by different reactions and are not related chemically to rubber.

The first view, i.e., that they are derivatives of rubber, is the one most generally held and is probably correct for high-grade rubbers, notably those obtained from *Hevea brasiliensis*. Tschirsch<sup>1</sup> states that the carbon and hydrogen in resins frequently stand in the same relation to one another as in rubber, which, since all resins contain oxygen, would indicate that they are oxidation products. Perhaps the best argument, however, is that the resins of *Hevea* rubber protect it from oxidation and subsequent tackiness. When they are removed by extraction and the rubber sheeted out thin and exposed to air it quickly grows tacky. If it

is again extracted it will be found to have regenerated its acetone soluble content. Oxidation is accelerated by ultraviolet light. If a thin sheet of rubber is exposed to air in the presence of ultraviolet light it becomes tacky and has a higher resin content than before exposure. This view is not concurred in by Hinrichsen and Marcusson, and probably will never be accepted as a general rule applying to all rubbers.

The second view is perhaps correct to a limited extent in all varieties of rubber. Probably when we understand the mechanism by which the plant produces caoutchouc we will be able to throw more light upon this theory. Many rubber resins, i.e., the acetone-soluble portion of rubber, are made up of two parts, a soft and a hard resin. These may often be separated by steam distillation, etc. The inference is that they are similar to the balsams which consist of a resin dissolved in an essential oil. The hard portion is likely an oxidation product of rubber similar to Spillers resin,  $C_{30}H_{48}O_{10}$ , or a separate substance produced by the plant by some other reaction. The soft material is probably a terpene with a low degree of polymerization, i.e.,  $(C_{10}H_{16})_n$  where  $n$  is very small.

The third theory is applicable to the resins obtained from highly resinous rubbers, particularly those obtained from *Dyera* varieties such as Jelutong, Pontianac, Dead Borneo, etc. In these varieties the function of the plant seems mainly to have been the production of resin with rubber merely as a by-product. Hinrichsen and Marcusson<sup>2</sup> attacked the question by investigating the optical properties of resins obtained from various rubbers. They found that all varieties examined except *Hevea* resin were optically active and dextro rotatory. They deresinated a sample of *Funtumia* rubber and exposed it to the air, bringing about oxidation and tackiness. On again deresinating they obtained 3.11 per cent of an inactive resin. The rotation for natural *Funtumia* resin is  $[\alpha]_D + 32.9$ . They concluded that since the oxygen derivative of rubber is optically inert this must be inert also and the active resins can not possibly be rubber derivatives. Optical activity is a characteristic property of the terpenes and the activity of natural resins is probably due to the presence of a small amount of such bodies.

#### PROPERTIES OF RESINS

*Resin Content of Various Rubbers:* The percentage of resin varies with the variety of tree and the care with which the rubber has been prepared. In general the more careful the coagulation the lower the resin content. Table I contains the resin contents and washing losses of certain rubbers as given by Spence<sup>3</sup>.

<sup>1</sup>Z. K. anorg. Chem. 22, 1916, p. 49.

<sup>2</sup>Proceedings, International Rubber Congress, 1914.

<sup>3</sup>Die Harze, 1906, vol. 1, p. 939.

Many others could be given but these are perhaps the most important. It should be mentioned here that Guayule and Jelutong (including Dead Borneo and Pontianack) where the only varieties ever detersinated on a commercial scale. The extraction of Jelutong yields such a large quantity of resin and so little rubber that it was early abandoned, at least as a source of rubber. The resin is valuable for certain purposes, and odd lots still find their way to the market.

**Ozonides of Resins:** Harries<sup>4</sup> states that a characteristic property of rubber resins is that they form ozonides insoluble in carbon tetrachloride and chloroform.

**Melting Point of Resins:** Most resins are liquid at ordinary temperatures. Dittmar<sup>5</sup> reports the following melting points:

|                   | Deg. C. |
|-------------------|---------|
| Congo Rubber..... | 74      |
| Borneo.....       | 92.5    |
| Madagascar.....   | 102     |

**Unsapnifiable Matter, Optical Activity, and Iodine Values:** The work of Hinrichsen and Marcusson has been mentioned above. The values obtained by them are as follows:

|               | Unsapnifiable Matter in Resin | Optical Rotation | Iodine Value |
|---------------|-------------------------------|------------------|--------------|
| Jelutong..... | 100%                          | (a) D + 50.9     | 30.6         |
| Cassia.....   | 92.5                          | Active           | .....        |
| Pedang.....   | 90.2                          | Active           | .....        |
| Guayule.....  | 78.2                          | (a) D + 12       | .....        |
| Kickxia.....  | 74.0                          | (a) D + 32.9     | .....        |
| Congo.....    | 56.0                          | (a) D + 12       | .....        |
| Ceylon.....   | 20.8                          | Inactive         | .....        |
| Para.....     | 15.0                          | Inactive         | 118.0        |

They found as a general rule that the more active optically the resin the more unsapnifiable matter it contained. The unsapnifiable matter in Upper Congo resin gave a rotation of  $[\alpha]_D + 24.5$ , while the sapnifiable constituent of the same resin gave only  $[\alpha]_D + 13$ .

#### CHARACTERISTICS OF CERTAIN RESINS

**Jelutong:** Dubosc<sup>6</sup> treated crude Jelutong with acetone and then with ether and obtained two products which after repeated crystallization were both shown to have the empirical formula  $C_{28}H_{48}O$ . They differed as follows: Melting points  $80^\circ$ - $82^\circ$ , and  $105^\circ$  C.; boiling points  $195^\circ$ - $200^\circ$ , and  $230^\circ$ - $290^\circ$  C. respectively; also in their solubility in acetone and chloral, and in their behavior with nitric and sulphuric acids. Dubosc considers that there is a simple relation between cholesterolin and purified Jelutong resins. He regards the latter as isomers of phytosterin or plant-cholesterin. Cholesterolin gives a characteristic color reaction with propionic anhydride. A blue color is first obtained which soon changes to red, then to green, then orange and finally red. With acetic anhydride a violet color is obtained, which eventually turns black. The resin propionate has a melting point of  $98$ - $100^\circ$  C. Cholesterolin propionate melts at  $98^\circ$  C. The resin acetate melts at  $110$  to  $112^\circ$  C. Cholesterolin acetate melts at  $113^\circ$  C. The resin acetate in common with cholesterolin acetate is sapnifiable with boiling water. The reactions of cholesterolin and Jelutong resin with sulphuric acid are analogous. Potassium permanganate, chromic acid, and sulphuric acid oxidize cholesterolin to acids soluble in ammonia. Jelutong, when boiled three or four hours

with the oxidizing mixture, is converted to cholesterolin acid, which is easily separated by means of ammonia. Fractional extraction of Jelutong with acetone in a Soxhlet yields three distinct products, melting at  $141^\circ$  C.,  $115^\circ$  C., and  $103^\circ$  C. A mixture of equal parts of the resins melts at  $82^\circ$  C. These bodies are isomers and have the empirical formula  $C_{28}H_{48}O$ .

Schidrowitz states that Jelutong contains a white crystalline hard resin soluble with difficulty in cold, but readily in hot absolute alcohol, and a soft yellowish resin very readily soluble in cold alcohol. Technically, hard resins are preferable to soft. A resin content up to 8 per cent is not serious if it is mostly hard. Funtumia elastica, properly prepared, contains only hard resin. Schidrowitz is of the opinion that Jelutong resin is probably a compound of vegetable cholesterolin with cinnamic acid.

The following analytical data was obtained by the writer on old Pontianack resin obtained in the open market:

|                           | A             | B             | C <sup>a</sup>  |
|---------------------------|---------------|---------------|-----------------|
| Melting point.....        | $73^\circ$ C. | $82^\circ$ C. | $92.5^\circ$ C. |
| Acid value.....           | 3.5           | 4.1           | None            |
| Saponification value..... | 70.0          | 48.1          | 28.1            |
| Iodine value.....         | 43.2          | 44.0          | .....           |
| Acetone soluble.....      | 99.5          | 99.3          | .....           |

<sup>a</sup> Reported by Dittmar for Borneo.

**Guayule:** The Guayule shrub, *Parthenum Argentatum*, contains 8 to 10 per cent of rubber based on dry material. The commercial rubber contains 75 per cent of rubber hydrocarbons. The dry plant, according to Alexander,<sup>7</sup> yields about 6.5 per cent of a dark-green substance when extracted with acetone. Of this 54 per cent, 31 per cent and 15 per cent are successively dissolved on treatment with light petroleum, ether and hot alcohol. Of the three component parts thus separated 12.1 per cent, 7 per cent and 2 per cent consist of unsapnifiable matter. The acids produced by the hydrolysis of the extract include one melting at  $119^\circ$  C., which belongs to the cinnamic acid group and phenyl acetic acid. Weil states that he found cinnamic acid in products of hydrolysis of Guayule resin. The crude acetone extract on steam distillation yields a sesquiterpene alcohol melting at  $127$ - $128^\circ$  C., which has a camphor-like odor.

On distillation with steam Guayule rubber yields from  $\frac{1}{2}$  to 4 per cent of a volatile oil ( $15^\circ$  C. .8861) which is laevo-rotary. You will note that Hinrichsen found the resin to be dextro-rotatory. This oil possesses a peculiar pepper-like aroma and consists almost wholly of hydrocarbons. On distillation at 17 mm. pressure it yields the following fractions:

|                                  | Per Cent |
|----------------------------------|----------|
| Between $50$ - $60^\circ$ C..... | 30.0     |
| $60$ - $80^\circ$ C.....         | 20.3     |
| $120$ - $160^\circ$ C.....       | 24.8     |
| Resinous residue.....            | 5        |

The first fraction is mainly l-piylene and the third a sesqui-terpene. No styrene is present. The above relates to the oil distilled from fresh Guayule. Oil distilled from plants which have been stored for several years contained much oxygenated material and while piylene was obtained no sesqui-terpene fraction could be isolated. The presence of volatile oil in Guayule is the cause of the difficulty experienced when the rubber was first used on an industrial scale, since it hinders vulcanization. The oil also causes trouble because of

<sup>6</sup>G. 2, 1910, vol. xxiv, p. 850.

<sup>7</sup>G. 2, 1907, vol. xxi, p. 666.

<sup>8</sup>La Caout. et la Gutta Percha, 1911, 8, 5756-5761.

<sup>9</sup>Ber. 1911, 4, 2320-2328.

its dissolving action on rubber during vulcanization. It tends to break down the rubber and depolymerize it. Guayule can be used in small quantities blended with other rubbers, but if it is to be employed alone it should be deresinated.

The following analytical figures are the average of results obtained by the writer with fresh Guayule resin over a long period of time:

|                      | Per Cent |
|----------------------|----------|
| Isoline value        | 57.5     |
| Saponification value | 61.1     |
| Acid value           | 20.5     |
| Unsaponifiable       | 50.1     |

### FUNCTION OF RESINS

In low-grade rubber the resin functions simply as a diluent. The rubber secured by deresination of Guayule, Pontianack, Jelutong, Palembang, or Dead Borneo is in every case of good quality, being about on a par with Brown Crepe. In high-grade rubbers, such as the plantation and Para varieties derived from the *Hevea brasiliensis* tree, the function of the resin is entirely different. The first effect is to protect the crude rubber against oxidation. Deresinated Hevea rubber when exposed to the air soon becomes tacky. The second is to assist in vulcanization. Deresinated Hevea rubber cured with sulphur requires a longer time or higher sulphur content than is customary. The acetone-soluble material from this variety of rubber is a good accelerator. The presence of resins is apparently necessary if the mineral accelerators are used. L. E. Weber<sup>1</sup> was unable to obtain a good vulcanization with deresinated rubber, sulphur, and litharge. The presence or absence of resin has very little effect on the time of cure if organic accelerators are used. The accelerating effect of Hevea resin has now been shown to be due to nitrogenous matter which is soluble in acetone. The influence of proteins and other nitrogenous materials has been well discussed by Dubosc, Eaton and Grantham, Beadle and Stevens, and others, to whose writings the interested reader is referred.

### FEASIBILITY OF DERESINATION

As indicated above, only low-grade rubbers were deresinated on a commercial scale; and of these only Guayule and the rubbers from *Dyera costulata* (namely: Jelutong, Pontiniac, Palembang and Dead Borneo) ever came into any prominence in this field.

Chute,<sup>2</sup> in estimating the cost of deresinating guayule in 1909 by his process, to be mentioned later, assumed that a grade yielding 60 per cent of purified gum could be purchased at 30c. per pound. He placed the solvent cost at 3c. per pound and the working cost also at 3c. per pound. One pound of Guayule would yield .6 pounds of gum at a cost of 36c., which made the cost per pound of finished gum 60c. The market price of guayule is still around 30c. per pound, but of course solvents, particularly acetone, are much higher. On the other hand, however, chemical engineering practice has made great progress within the past nine years. With modern apparatus the solvent loss should be reduced almost to zero. Based on a process later to be discussed, using gasoline and acetone, the solvent loss was seldom less than 15 gallons of acetone and 44 gallons of gasoline per 1000 pounds of good rubber produced.

The supply of Pontianack is today almost exhausted. This is due solely to the wasteful and extremely primeval methods used by the natives in securing the gum. Where they might have tapped trees and built up a steady business they felled and bled them at many different points. The method produced quick results but the procedure reminds one of the old fable about killing the goose that laid the golden egg. In 1909 a good grade of Ponti could be secured at 5c. per pound. The market price is now around 30c. per pound, making Ponti no longer a profitable purchase.

Chute<sup>3</sup> in 1909 estimated the cost of deresinating Ponti as follows: "Assuming that Pontianack can be bought for 5c. per pound and that it yields one pound of purified gum from ten pounds of the crude, then the materials cost (by his process) for the rubber will be 50c. per pound for the finished product. If one gallon of solvent per pound of crude gum is used and the solvent is worth 75c. and the loss is one per cent, then the cost for loss of chemicals calculated on the finished product would be 7.5c. per pound. The cost for labor and other expenses for a moderate-sized factory should not exceed 5c. per pound of finished product. This would give a total cost per pound of 62.5c." Crute based his estimate on the use of certain methyl and ethyl esters, but the figures are typical of results obtained in the past.

The deresination of Ponti is now not to be thought of, but aside from patriotic reasons the treatment of guayule should be a good business proposition. It is not nearly so difficult as the treatment of a low-grade gold ore. There is no reason why it cannot be successfully and profitably accomplished if suitable chemical engineering talent be obtained.

#### Statement of the Problem:

1. To deresinate guayule, one must reduce the resin content from approximately 25 to about 2 per cent.
2. The rubber must not suffer in quality by excessive heating or by detrimental action of any solvent or reagent.
3. Solvent and rubber losses must be kept as low as possible.
4. The operation must be accomplished in as short a time and with as few treatments as possible.

*Processes:* Many processes have been proposed in the past. They may all be classified under the following heads:

1. Those which depend on the action of alkali on the resins.
2. Those employing a mixed solvent which at high temperatures will dissolve rubber, but at lower temperatures is a better resin solvent.
3. Those processes which use a rubber solvent for dissolving both rubber and resin and then precipitate out the rubber by adding a resin solvent in which rubber is insoluble.
4. Those which first extract the resin and later remove the rubber from woody material, such as occurs in guayule, by a suitable rubber solvent.
5. Those which employ a solvent for resin without at any time dissolving or otherwise affecting the rubber.
6. Those which use a mixed solvent consisting of a rubber and a resin solvent. The first swells the rubber and the second removes the resin.

<sup>1</sup>Eighth Int. Cong. Applied Chem., 1912, vol. ix.

<sup>2</sup>H. O. Chute, "Deresination of I. R.," *J. I. R. W.*, June, 1909.

### 1. Alkali:

Processes using alkali depend upon the fact that certain of the rubber resins are partly saponifiable. Guayule resin, as reported by Hinrichsen (see above), is about twenty-two per cent saponifiable. Chaplet and Rousset<sup>10</sup> state that washing rubber with alkali after deresination removed some albuminoids and oxydases which would otherwise turn it black and oxidize it. Treatment with alkaline solutions is not a practical proposition; first, because it removes only a small part of the resin; and second, the removal of all the alkali is almost impossible. Even traces of caustic behave as unregulated accelerators, causing the stock to harden up and surface check on standing.

However, the first deresinating patents granted in this country were to Austin Day<sup>11</sup> in 1856 for purifying rubber gums by treatment with alkaline solutions. In 1857 Roberts Haerting received U. S. Pat. No. 17,214 for purifying gutta percha by the action of an alkaline liquor which, as he claims, dissolves out the etheric oil. In 1903 W. A. Lawrence received a series of patents beginning with U. S. Pat. No. 741,256 covering the extraction of rubber from plants (guayule) by treatment first with naphtha and then with a solution of caustic soda. No. 741,258, issued August 20, 1902, refers to a process by which the rubber is removed from the plants by mechanical means and the resins then dissolved by alkali or alcohol.

### 2. Solvent which will dissolve rubber at high temperatures:

This method is really much better suited to gutta percha than to rubber. Eng. Pat. 22,758 was granted in 1901 to Combanaire and de la Fresnaye and covers the purification of gutta percha by treatment with naphtha which at certain temperatures dissolves gutta resins. A similar patent<sup>12</sup> was granted to Wilmonsky in 1901 for a process of refining gutta percha, which consisted in dissolving the entire gum in hot gasoline and cooling to 60° F. when it was claimed if four gallons of naphtha or more were used for each pound of gum a flocculent precipitate was formed which consisted of pure gum.

Under this head may also be placed those processes which use pyridine. U. S. Pat. 983,812 granted to Drefus, Friedl and Bentley in March, 1910, describes a process wherein crude rubber is treated with six times its weight of pyridine base oil (boiling between 130 and 220° C.) and an equal weight of water. The mixture is agitated and heated to about 100° C. under a reflux condenser for 2 to 4 hours. Owing to the fact that pyridine even at this temperature dissolves appreciable quantities of rubber the process was never a commercial success.

### 3. Dissolve both rubber and resin, then precipitate the latter:

In February, 1906, a German patent was granted to Gratz covering a process in which the crude rubber was treated with benzine, turpentine, carbon bisulphide or gasoline, which dissolve both rubber and resin. The rubber is precipitated by the addition of methyl, ethyl or amyl alcohol which holds the resins in solution.

U. S. Pat. 978,696 issued to L. H. Chanut in June, 1910, describes the successive treatment of crude gum

with carbon bisulphide and acetone. For 100 Kg. of crude in all 227.5 litres of carbon bisulphide and 334.1 of acetone were required. The gum was first worked in a dough mixer with 50 litres of carbon bisulphide; later 40 litres of acetone were added and mastication continued. The mixture of solvents was poured off, 97.5 litres of CS<sub>2</sub> added, and mastication resumed. After a time 50 litres of acetone were added, thus precipitating the rubber. The solvents were poured off and 20 litres more of acetone added, which was poured off after a brief mastication. The third and fourth treatments began with 40 litres of CS<sub>2</sub>, followed by 56 litres of acetone. The mixed solvents were poured off and 56 litres of acetone added in each case as a sort of after-wash to remove resins and granulate the rubber.

Another process belonging in this group is that of Lawrence,<sup>13</sup> in which guayule which had been previously removed from wood by solution in naphtha was treated with alcohol which precipitated the rubber and dissolved the resin. After thoroughly washing the rubber to remove the last of the resin the solution was evaporated, leaving the resin behind in the kettle.

### 4. Extraction of the resin, followed by removal of the rubber from the wood:

This process is the opposite of that of Lawrence mentioned above. Foelsing<sup>14</sup> proposed to extract the ground Guayule shrub with acetone followed by removal of the rubber by solution in naphtha. The solvents were removed by evaporation.

Both these processes are of rather questionable value owing to the fact that they could only be carried on in the region where Guayule is harvested, which territory is not very satisfactory for extensive chemical operations. The solution processes for separation of rubber from Guayule shrub have nearly all been abandoned in favor of mechanical methods.

### 5. Extraction with a resin solvent:

These processes are modifications of analytical procedure for determining the percentage of resin in crude rubber, which subject was investigated by C. O. Weber,<sup>15</sup> who concluded that acetone is the most satisfactory resin solvent, and states that it will, particularly at higher temperatures, easily dissolve all the resinous constituents of rubber, gutta percha, and balata without dissolving a trace of any of these bodies themselves. The processes under this head involve the extraction of rubber with acetone, alcohol, or other resin solvent which does not attack the gum.

The first patent granted in this country in which definite claim to deresination of rubber was made, was the one previously mentioned which was granted to Lawrence<sup>16</sup> in 1902. It involved the treatment of guayule containing some naphtha with alcohol. The extracting plant consisted of a churn which was provided with a corrugated bottom with corrugated rollers which in passing over it masticated the rubber in the presence of the solvent. The saturated liquid was removed to a still, the acetone and naphtha evaporated and run into tanks for further use, leaving the resin behind.

A process closely related to analytical practice is that of Eves<sup>17</sup> in which a car containing rubber is exposed

<sup>10</sup>LeCaout, *et la Gutta Percha*, Feb. and Mar., 1911.

<sup>11</sup>U. S. Pat. 15,067.

<sup>12</sup>U. S. Pat. 673,320.

<sup>13</sup>U. S. Pat. 741,260, Mar. 1902.

<sup>14</sup>French Pat. 368,958 (1906).

<sup>15</sup>"Chemistry of India Rubber."

<sup>16</sup>U. S. Pat. 821,934, issued 1906.

to the vapors of alcohol or acetone which pass through and around the mass which is worked by rotating arms within the car. The condensate falls from the condenser upon the rubber, thus giving extraction at or near the boiling point of the solvent, which point was particularly recommended by Weber.<sup>15</sup> At least one large plant was successfully operated under the Eves patent and several hundred tons of rubber were treated by this process.

Practically all deresinating plants in operation in this country in 1912 used acetone as the resin solvent. Of particular interest now are the patents of Chute<sup>16</sup> which cover the use of the acetic esters of ethyl and methyl alcohols. He states<sup>17</sup> that acetone will dissolve when hot only 18 per cent of Pontianack resin, some of which will crystallize out on cooling. Methyl acetate dissolves 25 per cent of the resin and ethyl acetate 50 per cent. These esters were used in conjunction with acetone. In other words, Chute discovered a mixed solvent which has no effect on rubber but holds a high percentage of resin. The chief objections to the use of these esters are their high price and the relatively small quantities available. Solvent loss was formerly quite a factor, but with modern apparatus this should be reduced to a negligible factor. If deresination by means of a resin solvent is decided upon the mixed solvents of Chute would probably be superior to acetone since smaller volumes of solutions could be handled, requiring less equipment and giving a lower solvent loss.

6. *Two solvents, one to swell the rubber, the other to dissolve the resin:*

The processes which come under this head were in general use and a rather large volume of deresinated Guayule was prepared in this way. The resin solvents employed were chiefly alcohol or acetone, while gasoline was used almost entirely for swelling the rubber. They were combined and used as a mixed solvent. The usual proportions were 47 per cent gasoline and 53 per cent acetone by volume.

You will note that the Lawrence<sup>18</sup> patent also comes under this classification. The idea is indicated, though rather imperfectly described, in French Pat. 404,307 (1909) to the Caoutchouc Co., which describes a process in which a little benzine is added to soften and swell the rubber to the gelatinous condition but not enough to dissolve it, after which acetone was employed to remove the resins. The process described later in this paper also comes under this classification.

*Apparatus:* All those who are familiar with the preparation of rubber cements realize that no solvent can properly act on large masses of rubber without constant mastication. This principle is of the greatest importance in deresination, no matter which process is used. Means must always be provided for bringing the solvent in intimate contact with the rubber. The closed vessel in which the rubber and solvent are worked together, usually by rotating arms or rollers, is called the churn.

U. S. Pat. 821,717 was issued to F. C. Hood in 1906 for such an apparatus. A set of ordinary rubber washing rolls were mounted in a water-tight covered chamber which was filled with deresinating liquid to a point above the rolls. The sheet of rubber was made to pass through the rolls, then up and through once more,

There is also a patent to Lawrence,<sup>19</sup> previously mentioned, for a corrugated roller passing over a corrugated bottom.

Whether the treatment in the churn is continuous or intermittent, the solvent soon becomes charged with resin from which it must be separated by distillation. A still has been designed for this purpose by Chute<sup>20</sup> with the special purpose of preventing foaming, which would carry some of the resin into the distillate. It is a combination of a chambered column still, provided at its base with a quieting and settling chamber which is connected to a sort of boiler through a large tube. Vapor from the boiler enters the settling chamber near the top.

Chute<sup>21</sup> has worked out a process which is especially suitable for his mixed resin solvent, i.e., acetone with ethyl or methyl acetate. The apparatus comprises a series of extractors provided with means of heating and mastication. The solvent is admitted to the extractors on the counter current principle, with a view to treating the rubber in each at least four times or more. The process permits the treatment direct of crude rubbers without drying, since it has been found cheaper to remove the moisture by use of solvents than by drying in the ordinary way. Price calculations on Guayule and Pontianack have been previously discussed.

(To be Continued)

## Chemists to Discuss War Necessities

Coincident with the Fourth National Exposition of Chemical Industries to be held in Grand Central Palace, New York City, during the week of Sept. 23 will be held various conventions of chemical and technical organizations. The meeting and programs will reflect the strides made by the chemists of America during the past year. The exposition also will show the people of the country the remarkable expansion which the chemical industry has undergone, as it will be necessary to use four floors of the building for the exhibits.

The exposition is a war-time necessity; and regarding it as such each exhibitor is planning his exhibit so that it will be of the greatest benefit to the country through the men who visit it, all of whom are bent upon a serious purpose—that of producing war materials in large quantities, and constantly increasing this production till the war has been won by the United States and its allies.

Papers covering practically every phase of chemistry and a discussion of steps that will need to be taken after the war will be presented by leading experts in each branch. Pressing chemical problems concerning many of the chief articles of domestic and foreign commerce will be taken up during the convention, and it is expected that these discussions will have an important bearing on the future manufacture of materials that have been scarce and high-priced ever since the curtailment of American commerce with Germany and other European countries. In order to fill the demands for chemicals hundreds of factories have sprung up in various parts of the country, and while doing a large business, it is pointed out by experts that there is a lack of preparation to meet new conditions which are bound to follow at the close of the war.

## The Human Element in the Mill

Influence of Competition on Process Control Records—Importance of Automatic Recorders and Working Diagrams—Creation of Research Initiative

MANY important ideas of vital interest to mill executives were brought out in the opening address by HUGH K. MOORE at the tenth annual meeting of the American Institute of Chemical Engineers. Mr. Moore spoke of the relation between manager and employee. The following extracts are printed verbatim from the address which will be published in full by the society in the 1918 annual.

### IMPORTANCE OF MENTAL CONTACT BETWEEN MANAGER AND MEN

If you only know what the men think you may be able to make explanations which will enlighten them and give them a different outlook on life. The closer the personal touch between the employer and employee the less is the chance for misunderstandings and the better for both employer and employee.

Do you realize that a man may put down figures which he knows are not the truth and yet never have it enter his mind that he is sophisticating his results? This is not dishonesty because he does not perceive there is any dishonesty in what he has done.

An example of this may be taken from our 1908 records. The operation is burning sulphur with air with the intent of getting the highest possible percentage of sulphur dioxide in the resulting gas. The records on our books show the following results as obtained from hand-fired flat burners used at that time.

| PER CENT SULPHUR DIOXIDE GAS |                  |                 |  |
|------------------------------|------------------|-----------------|--|
| Shift 12 N. to 8 A.M.        | 8 A.M. to 4 P.M. | 4 P.M. to 12 N. |  |
| 15.8                         | 15.6             | 16.5            |  |
| 15.0                         | 18.4             | 14.6            |  |
| 16.6                         | 16.3             | 11.6            |  |
| 15.8                         | 13.9             | 17.3            |  |
| 15.8                         | 16.3             | 16.6            |  |
| 15.8                         | 15.3             | 17.3            |  |
| 15.8                         | 16.2             | 17.2            |  |
| 15.0                         | 17.2             | 16.1            |  |
| 14.0                         | 12.6             | 16.4            |  |
| 16.4                         | 15.3             | ...             |  |
| Average 15.6                 | 15.7             | 15.9            |  |

You will see from the above that there is not very much difference between the maximum and minimum readings.

To show that the above is not a true statement of facts, I submit Chart I giving the analyses from a recording machine. It will be observed that the figures given in the above table are only the maximum figures. You see every time the burner doors were opened the large influx of air weakened the gas. Now every foreman soon found out that after a certain time had elapsed after firing, the gas would test a maximum and not sublime sulphur. He always planned then to be on hand at this time to test his gas and actually put down the figures he found by analysis. This in all probability started from one foreman doing this and when the other foremen did not get equally good results they copied the same method. Now these men were not scientifically trained, and when they averaged up their selected results there was no thought in their minds that they were

of no value whatever. Furthermore the management, on going into the mill and seeing the foreman write down the selected results which he could see were actually obtained on the Orsat, had no suspicion as to how far they were incorrect. Had he known what the men were thinking about he would have been "put wise," and would not have accumulated on his books an amount of data which was absolutely valueless. At this time we had installed an automatic recorder. The recorder record of the same shifts shows far different results though the maximum results are approximately the same. Comparing the two we get results as follows:

| PER CENT SULPHUR DIOXIDE |         |          |
|--------------------------|---------|----------|
|                          | Foreman | Recorder |
| Shifts 8 a.m.—4 p.m.     | 15.7    | 11.5     |
| Shift 4 p.m.—12 n.       | 15.9    | 13.1     |
| Shift 12 n.—8 a.m.       | 15.6    | 12.9     |

Incidentally this illustration shows the value of an automatic machine which records at given definite intervals. Even had the management known of these variations it would have been unable to time the analyses of the different foremen periodically so as to get true concordant results. In the case above (which is given not as an isolated case but as an example of a type) we have an illustration of ignorance, combined with the idea to make as good a showing as possible based on the more or less ever present feeling of self-preservation. Where the superficial observer would have classed the foreman as dishonest the careful observer cannot overlook the psychology involved. It sometimes happens that the management expects too much of the men. By this I do not mean to state that he does so purposely; in fact, he is unaware that he is expecting too much. He probably does not know the complexity of the problem involved and what is more even if he were on intimate terms with his employees he could hardly find it out as they do not know themselves just what is involved and cannot make it clear to their employers. Here is where the chemist or chemical engineer comes in. He, however, should be democratic, of sterling character, and in full sympathy with his fellow beings. He can then obtain from them what information they can impart and with his more technical knowledge reject that which is bad and adopt that which is good. Above all he should not be a man, "who knows it all." The man who goes around with the air of "I know it all" engenders antagonisms and often contempt and discourages suggestions. He may defeat by this attitude the main object of accomplishment which is his task.

The man constantly with a process or apparatus finds out many details of operation which one who is not constantly in touch with it (no matter how able he is) will hardly find out at all. In my experience in mill work I have never run across a man operating a process or device that could not show me valuable points. A lot of opposition to changes which the man-

agement wishes to make may be traced to the fact that the management has not taken care to collect the valuable data which their employees have. They consequently do not know what their men are thinking.

As an illustration I know of a manager who, noticing that knots and bark sank while chips of clear wood floated, designed a process for their separation by flotation. He told the foreman of his scheme who promptly told the manager it would not work, at least not to such an extent as to make it practicable. The manager, an educated man, thinking it was the ever-recurring opposition to innovations, turned on his heel and left the foreman without asking for an explanation. He constructed his machine, installed it, and tried to operate it, and on finding that it would not work finally destroyed it. Later he called the foreman and asked him how he knew it would not work. The

sum of these is also plotted. By plotting in this manner we can illustrate our point and yet simplify the matter to such an extent that it is readily understandable to those who have not, so to speak, made a profession of the study of numerous and complex graphs.

The efficiency curve is the only one known to the foremen and the dotted lines were known only to the investigators. Smith, Brown and Jones are fictitious names.

To the foremen the efficiency meant the amount of water evaporated per pound of coal and this was arrived at by metering the water into the boiler and dividing the same by the pounds of coal used.

It will be seen from the above chart that Smith was an honest man and the amount of heat accounted for did not ever get to an amount over 100 per cent of the heat in the coal that could be accounted for,

CHART 1—ANALYSIS OF RESULTS FROM A RECORDING MACHINE

foreman took a piece of wood floating in the wood-room tank and cut many chips from the same. They, when thrown into the water, went to the bottom. This foreman from his daily work had observed certain facts which had escaped the attention of the manager. This manager made the mistake of underestimating the intelligence of his foreman. Some see and remember the minutest details, while others may miss these entirely and pay attention only to the principles involved. The strict observance or non-observance of detail is often, in fact is generally, the difference between success and failure, provided your basic principle is sound.

In the illustration before given we have shown a typical case wherein men put down results which they knew did not represent the facts and were entirely honest in what they were doing.

I am now going to give a typical example of wilful sophistication and will illustrate it by Chart 2 which shows more or less accurately the efficiency of the foremen on each shift in the boiler house. This chart is only illustrative, for in order to save space and in the interest of lucidity it is condensed in time and all the factors are not plotted; radiation, convection, the necessary blowage, etc., are not plotted but lumped together in a constant called radiation 5 per cent.

The stack losses and the ash losses and the efficiency of the boiler are plotted all in terms of the percentage of B.t.u. contained therein of the original coal, and the

save by errors in observation and calculation. On the fourteenth and fifteenth day Jones probably, by accident rather than design, blew off more water than was customary. On the sixteenth and seventeenth he ran normally and probably cogitated on the fact of his high efficiency. In his cogitations it occurred to him that he had blown an unusually large quantity of water when he obtained a high efficiency and from then on Jones purposely blew an ever-increasing amount of water through the blow-off.

Brown also had been cogitating over the high efficiency of Jones and finally gets wise but he overdoes it and his efficiency jumps to 86 per cent. Now the graphic department in plotting all the curves noticed that the total B.t.u. accounted for reached as high as 110 per cent of the B.t.u. in the coal. They report it to the chemical engineer and he sees where the plant is not complete and perhaps he talks with Smith. At any rate, on the twenty-seventh he installs a tank capable of standing the full pressure of the boiler and pipes the blow-offs of the boiler to this tank. By this means certain deductions can be made and the efficiency as figured from the input of water to the boiler is corrected. It will be observed that the efficiency of both Brown and Jones dropped while that of Smith did not change upon installing the tank.

I have given an example of the management underestimating the intelligence and powers of observation of the employees. To underestimate the difficulties

encountered by the men, while perhaps not of as great importance as the foregoing is still of sufficient importance to warrant its mention.

#### WORKING DIAGRAMS

In all probability most chemical and metallurgical operations are carried on by men who have had no training in chemistry or metallurgy. By long experience a man may obtain a technique which will enable him to carry on an operation successfully even though it may be complicated by many variables. Now if these men are organized they may, if they so desire, exert a pressure on the mill management all out of proportion to their numbers. This is especially true if the operation they control is a fundamental part of the operation of the plant. I have seen the time when six men not only had the power but exerted it to shut down the largest mill of its kind in the world. Realizing this fact, they made most exorbitant and

pressure. When we first started this system we found it very difficult to make the men understand that a pressure below atmospheric pressure was a real pressure, so we plot those pressures below atmospheric pressure as minus pressures, and a table of the pressures corresponding to temperatures of steam is given to every cook. Thus, 158° F. would show as pressure on this chart as -10 pounds while 250° F. would show as +15 pounds. Now the gage pressure<sup>1</sup> is plotted and the steam pressure<sup>2</sup> corresponding to the temperature is also plotted. The difference between these two is the gas pressure which is also plotted. Then inasmuch as it is the SO<sub>2</sub> gas which does the cooking this picture shows the cook if he is blowing off his gas too fast. The crosses on the chart are given in place of figures for the reason that we are dealing in principles and it is not our object to give away private information of the mill. The cooks are taught to plot these charts themselves and in so doing they correct their cooking procedure. Having established the value of the chart we at once placed ourselves in a position to demand uniformity of results. This example is an illustration of how the management formerly expected too much of the men, when they asked for greater uniformity of results than they got.

This chart has another value in that it is now possible to do experimental work in the laboratory and draw the desired chart which we may reasonably expect the cooks to duplicate in practice.

#### CREATING TECHNICAL INITIATIVE

There is a great tendency in manufacturing plants to hide the light of employees under a dark bushel basket. This is a narrow and shortsighted policy and while the management may save a few dollars in salary the intangible loss far outweighs the small amount saved.

As an illustration of what I mean I may give the policy of our own research laboratory as compared with the general attitude of laboratories over the country. When we hire a man we try to impress upon him that in considering his compensation he should not consider his salary as his total compensation. The reputation which he is enabled to make is as much a part of his compensation as his salary. We do not stand in the way of a man obtaining a wide reputation; we even aid him to get the same. This not only gives him an idea of what he is worth by enabling him to receive offers from the outside world which he otherwise would not have received, but it also informs the management that if he is worth so much to an outside organization he is worth as much or more to our organization. You will say, "I can see how this benefits the employee, but how does any such policy benefit the mill?" The answer is that such a policy tends to produce what I may term the Stimulation of the Initiative. And above all this policy tends to create respect and con-

CHART 2—BOILER PERFORMANCE CURVES FOR THREE FOREMEN

unscrupulous demands. Here again had the management possessed the information which the men had obtained, this thing would have been impossible. Now here is an operation containing many variables with the possibilities of spoiling a cook far in excess of the possibilities of making a cook, and with so many variables the probabilities are that though they may get by on making the cook, the products of separate cooks are not uniform but may vary greatly. Now if you want a carpenter to make a house you do not cut all his lumber for him and tell him "Everything is ready, now build your house." The carpenter would tell you to give him the picture or plans of the house and he could cut the lumber himself.

In the same way the operator of a complex chemical operation would like if it is possible to obtain a picture or plan of this operation. The more complex the operation the more ingenuity must be exercised to obtain a picture which means something. As an illustration, Chart 3 shows an actual digester cooked in 1911. On this chart the ordinates are pressures and the abscissæ are time in hours. The three pressures plotted are gage pressure, steam pressure and gas

<sup>1</sup>It will be observed that the steam pressure and gage pressure are on a different scale from the gas pressure and to this extent the chart is deceptive to the eye. To make these on the same scale the gage pressure and steam pressure should be 14.7 pounds higher.

<sup>2</sup>Just how this came to be plotted this way I do not know. However, the gas pressure is correct, which, of course, is the main thing. The cooks have formed the habit of making charts this way and as a change of chart to a more scientific scale would not in the end enable them to make better cooks and would during the process of changing tend to have them make worse cooks it has not been thought advisable to make the change.

fidence which are the foundation stones for loyalty and good service. We find first that the policy outlined not only informs the employer what he is worth but it informs the employee. It is very natural that an employee should get an exaggerated idea of his own importance. If, however, he finds that others besides his employer do not accept him at his own valuation he will modify his ideas. He can no longer take the attitude that if he could get out into a wider world that he would be more appreciated.

His reputation is what he makes himself and he receives full value according as he makes his reputation. Having now obtained a more or less true estimate of his own value he immediately starts to build up for himself a reputation and this can only be done by rendering valuable service. Here then may be a starting point for the development of the initiative. But it is not sporadic attempts which cause development; it is the constantly exerted force of the will which must be applied to allow physical growth to take place with the consequent mental growth. A dissatisfied employee will never exert the constant effort of the will to develop, even though it be in his own interest as well as his employer's. As an example of the application of the following principles I wish to state that in one of our mills our chemists began to develop the much-desired initiative. I was called away and was constantly out of touch with these men for four years and did not see much of them for two years more. During this time the man to whom they were directly accountable also tried to develop in these men the personal initiative, but defeated his own purposes by not giving the men the credit which was theirs.

Instead of taking out joint patents with these men he took them out in his own name, and while he talked and lectured on mill organization he never gave due credit to those who helped in this work, and while as a rule he did not claim directly all credit for this work, he nevertheless got the entire credit by implication. The result of this procedure was the entire destruction of the incentive, which stopped the development of the initiative. During this entire time there is no credit to this concern for patents taken out by these men, neither so far as my knowledge goes are there any publications by which these men could receive due credit from business men and others in their profession for that which they had accomplished. It is our problem to make conditions such as to recreate as far as possible the lost initiative. This is a far more difficult problem than formerly because the nerve tissues are less plastic and less susceptible of change by excitation than was their condition eight years ago. In the formation of habit it is essential as far as possible to avoid misdirected habit which becomes more or less of a stumbling block. Right here I wish to state that it is a great mistake to put a man in charge of the execution of a problem on which he has formed the preconceived opinion that its successful solution will be impossible. The successful solution of a problem may or may not be possible, but if you have determined to try and solve this problem after hearing all arguments pro and con, then the way to start is to put its execution in charge of a man who is an optimist as far as this particular problem is concerned. Here again we have an illustration of habit.

Every failure of the man who believes this cannot be done, and there will be many, will only tend to confirm him in his preconceived belief that it cannot be done, and repeated failures simply stimulate the habit of unbelief as far as this problem is concerned. We have seen a very good illustration of this principle in the

CHART 3

last three years. We had such a problem and the superintendent of one of our mills put a man of marked ability in charge of its execution. The marked ability of this man was recognized by the government sending him to France, putting him on General Pershing's staff as a chemical engineer with the rank of captain. Nevertheless he was a pessimist as far as this problem was concerned and nothing but discouraging results were forthcoming. When he left, the solution of this problem was sought by the same staff with the exception of this man and solved with the greatest success. The remark which he made upon being told of the successful solution of the problem, viz.: "I am from Missouri, you will have to show me," illustrates his mental attitude as far as this problem is concerned.

Now when you realize that mental growth is the product of constant application of the mind, you will readily see that the management, if it gives up a problem too soon, before opportunity for mental development has had a chance to take place, makes a great mistake.

I worked on one problem off and on for seven years; on another problem I worked three years and on the one just mentioned over three years. Two is a short time to solve a real big problem. Now from what has been said it will be seen that the changing of an executive in charge of a problem, unless he proves himself radically unfit, simply because he does not arrive at the solution immediately is a grave mistake. The executive has this problem before him night and day and the constant excitation of this part of his brain is producing a slow but nevertheless sure development which, if the problem is not impossible, must lead in time to its solution. Now if constant changes are made among the men in charge the new man has to go through all his predecessor went through before he has reached the same mental development. If then other changes are made the foregoing is repeated and the management has nothing to its credit but a large experimental expense. The management should be careful in choosing the man who is put in charge, but having chosen a man it should continue this man on this problem until results are achieved or until it has made up its mind that a successful solution will not pay dividends on the amount of money required for its solution. As mills go, far too many problems are abandoned before a fair trial has been given, owing to the non-observance of these principles.

I have spoken here of the mental attitude of the executive in charge of the successful solution of a problem, and laid down the principle that he should be a believer in its successful solution from the start, and now I want to say one word as to the attitude of the management in regard to suggestions coming from those responsible to it. It must be constantly borne in mind that the management puts its capital in these operations and that it will suffer for all mistakes it makes as well as the mistakes of its employees and that consequently its decision should be final, good or bad. But it often happens that it can reap benefit from the mistakes it makes as well as penalties. The wise management will allow certain leeway (within certain limits) to its chief executives as they, after all, carry out the policy of the management.

For instance, a foreman may come to the executive with a proposition which that executive knows from past experience will not work. He may turn it down absolutely or he may consider after figuring it over that he will allow the foreman to try it and fail and convince himself. I have done this many times myself and have obtained results from the changed mental attitude of the men which far outweighed the small expense involved and sometimes I have seen how to make suggestions from the failure which may change the failure into more or less of a success. In case of foreordained failure, so to speak, I always put it up to the man himself and give him my heartiest support so that when it fails he can have no comeback. If, as sometimes happens, the management is mistaken and the man gets the solution, the executive should not be

grudging of his acknowledgement, but take off his hat to him, so to speak, in a wholehearted manner. This tends to produce not only co-ordination but co-operation and the *esprit de corps* which we are striving to obtain.

## Gases Used in Warfare

In an article by Major S. J. M. AULD, entitled, "Methods of Gas Warfare," published in the *Journal of the Washington Academy of Sciences*, Feb. 4, 1918, the following list of gases is given as being used by the Germans in the present war.

1. Allyl isothiocyanate (allyl mustard oil)  $C_3H_5NCS$  (shell).
2. Benzyl bromide,  $C_6H_5CH_2Br$  (shell).
3. Bromoacetone,  $CH_3Br.CO.CH_3$  (hand grenades).
4. Bromated methyl ethyl ketone (bromketone),  $CH_3Br.CO.C_2H_5$  or  $CH_3.CO.CHBr.CH_3$  (shell). Dibromketone,  $CH_3.CO.CHBr.CH_2Br$  (shell).
5. Bromine,  $Br_2$  (hand grenades).
6. Chloroacetone,  $CH_3Cl.CO.CH_3$  (hand grenades).
7. Chlorine,  $Cl_2$  (cloud).
8. Chloromethyl chloroformate (palite),  $ClCOOCH_2Cl$  (shell).
9. Nitrotrichloromethane (chloropicrin or nitrochloroform),  $CCl_3NO_2$  (shell).
10. Chlorosulphonic acid,  $SO_2Cl.OH$  (hand grenades and "smoke pots").
11. Dichlorodiethylsulphide (mustard gas),  $(CH_2ClCH_2)_2S$  (shell).
12. Dimethyl sulphate,  $(CH_3)_2SO_4$  (hand grenades).
13. Diphenylchlorarsine,  $(C_6H_5)_2AsCl$  (shell).
14. Dichloromethyl ether,  $(CH_2Cl)_2$  (shell).
15. Methylchlorosulphonate,  $CH_3ClSO_3$  (hand grenades).
16. Phenylcarbylamine chloride,  $C_6H_5.NCCl_2$  (shell).
17. Phosgene (carbonyl chloride),  $COCl_2$  (cloud and shell).
18. Sulphur trioxide,  $SO_3$  (hand grenades and shell).
19. Trichloromethylchloroformate (diphosgene, superpalite),  $ClCOCCl_3$  (shell).
20. Xylol bromide (tolyl bromide),  $CH_3.C_6H_4.CH_2Br$  (shell).

## Rulings on Importation of Magnesite and Manganese

The War Trade Board has amended the restriction upon the importation of magnesite to permit its importation, under the back-haul proviso, when shipped as return cargo from Europe and the Mediterranean coast of Africa, and when shipped from convenient ports where loading can be done without delay.

Importations of manganese ore from Asia and Australasia have, by another ruling, been prohibited as to ocean shipments made on and after July 20, 1918; and, to make this ruling effective, all outstanding licenses for the importation of manganese from those countries have been revoked as to ocean shipment on and after July 20, 1918.

Adequate supplies can be obtained, it has been found, from sources near by, entailing far less strain upon the tonnage resources of the United States during the present difficult period than shipments from the distant ports in Asia and Australasia.

## Synopsis of Recent Chemical and Metallurgical Literature

**Molybdenum Steel.**—Discussing Dr. H. M. Howe's recent A. I. M. E. paper on "The Erosion of Guns", Mr. H. R. BATCHELLER said that ten years ago it would have been hard to determine molybdenum in steels containing considerable amounts of nickel and chromium. "A 1907 analysis of ferro-molybdenum by commercial methods gave what purported to be the following results: iron 92.55; carbon 5.64; molybdenum, trace. It subsequently developed that the 'carbon' was mostly molybdenum. The consulting chemist was C. T. Hennig, a former employee of Krupp, who represented them in this country in certain technical ways with special relation to molybdenum, chromium and manganese. The firm producing this ferro-molybdenum was offered a contract for the sale of its whole production to Krupp, who used it for ordnance purposes and would have been glad to get more. According to Hennig, the physical properties of the steel were improved by the addition of molybdenum just before pouring; he also said that analysis would often show only a trace of molybdenum in the steel, while the slag would be high and some molybdenum would be volatilized, especially if the molybdenum were added in the form of metal and not as ferro-molybdenum. When using the metal, it was, therefore, necessary to protect it from oxidation by plating, and silver plating was used successfully."

**Corrosion of Aluminium.**—At a meeting of the Society of Chemical Industry in London, Messrs. RICHARD SELIGMAN and PERCY WILLIAMS gave an account of the reaction between aluminium and anhydrous organic hydroxyl compounds such as the fatty acids, phenols and alcohols. The effective protection from corrosion afforded by the thin coherent coating of  $Al_2O_3$  on the aluminium is what makes this very reactive substance an industrially useful metal. As would be expected upon considering the reactions,

from the point of view of mass action, both of these would go to the right, were they initially started by decreasing the  $H_2O$  content to a sufficiently low point. Attention was brought to the subject by the failure of aluminium to resist corrosion in phenol concentrating distilling equipment. Some use can be made of this reaction for producing aluminium oleate, stearate, etc., as these acids, when anhydrous, react immediately with aluminium.

**Corrosion of Lead.**—In the discussion of the corrosion of lead before The Society of Chemical Industry<sup>1</sup> the fact was brought out that the sheet lead of old London roofs had decomposed where they were in contact with oak or portland cement. Condensation of moisture with wood acids and  $CO_2$  produced re-

sults similar to the Dutch White lead process in the former case. In the latter, sufficient alkaline salts are present to change the metallic lead to plumbites and plumbates. At the present time, sheet lead for chemical work has from 6 to 10 per cent antimony alloyed with it to increase stiffness to prevent creeping. In acid work, fluorine and silica must be prevented from being present, since hydrofluosilicic acid violently attacks lead.

**Aluminium in Germany.**—Low grade alumina ores are reported as being refined at the Neuhausen Works by means of the Moschicki process, by which producer gas is used as a reducing agent with the formation of aluminium nitride. Upon hydrolyzing, pure alumina and ammonia are obtained as in the Sepek synthetic ammonia process. The alumina is then reduced in an electric furnace as usual. Perhaps some such process can be used for obtaining alumina from certain clays, such as halloysite, which is abundant in the United States, and, according to Mellor, decomposes into alumina and silica at 350 degrees Centigrade.

**Variation of Young's Modulus with Temperatures.**—H. L. DODGE has presented four papers in *The Physical Review*, second series, Vol. 2, p. 431; Vol. 5, p. 373; Vol. 6, p. 312; and Vol. 11, p. 311, on the relation existing between temperature and elasticity of copper, mild steel,

aluminium and drawn tungsten, respectively. In the last paper he describes a new electrically-heated tube furnace for the work whose construction approximates that of a black-body. The wire under test is observed through mica windows in the furnace wall. Preliminary experimentation consisted of measuring the coefficient of expansion (found to be 0.00000456 per degree C.) In measuring the modulus of elasticity, the wire was uniformly heated from end to end by the passage of a constant electric current, and the temperature determined by its thermal expansion. The value of Young's modulus at 20 deg. C. ( $35.5 \times 10^{11}$  dynes per square centimeter) is lower than that given by Fink, but it is probable that tungsten wires prepared by different workmen differ that much in physical properties. The figure collects the results of all four metals graphically.

## Recent Chemical and Metallurgical Patents

**Distillation of Wood Tar.**—ROBERT C. PALMER, of Pensacola, Florida, patents the process of adding to wood tar a suitable amount of water and chemical catalyzer such as phosphoric acid, and distilling the mixture, whereat the complex combinations of phenyl, methoxyl, etc. radicals are hydrolysed to methyl alcohol and acid phenol, condensing the vapors and recovering a better yield of alcohol, acetic acid, phenols and tar oils. (Assigned to the public; 1,271,071. July 2, 1918)

**Manufacture of Alkali and Organic Chlorides.**—K. P. McELROY, of Washington, D. C., patents a process for the simultaneous manufacture of alkali and organic chlorides. A tank 20 (Fig. 1) is subdivided by diaphragms so as to make a succession of chambers containing anodes A of crushed carbon, cathodes C of wire mesh, and between each pair an electrolyte of brine. The electrolytic compartments are made

FIG. 1

narrow especially to diminish energy losses in overcoming the resistance. Furthermore, the polarization effect of the chlorine collecting on the anode is continuously neutralized by leading purified oil gas successively through the anode chambers by pipes 28, 29, 30 and 31. The olefins on contact with chlorine may react in either of two ways. One is a direct combination with it to form olefin chlorides, ethylene,  $C_2H_4$ , thus gives ethylene chloride, or "Dutch liquid,"  $(C_2H_4Cl_2)$ , a heavy oily body insoluble in water and having an odor and many other properties resembling those of chloroform. The other reaction is one in which water takes part and a chlorhydrin, or chlorinated alcohol, is produced. A molecule of chlorine,  $Cl_2$ , reacts with  $HOH$  and  $C_nH_m$ , to produce  $HCl$  and  $C_nH_mOHCl$ , or a chlorhydrin. The actual reactions at the anode vary with conditions; with a high current density chlorine may form as a gas. With an ample amount of water vapor chlorhydrins are formed. The recovery and separation of the separate products also depends upon the degree of formation and the use to which the product is to be put. (Assigned to Chemical Development Co., 1,264,536; Apr. 30, 1918.)

**Process of Making Exchange Bodies.**—GEORGE RUDOLF of London, Eng., notes that many natural silicates contain more or less zeolite which is a very active "exchange body." These minerals are very

useful in purifying water; an exchange takes place between the calcium and magnesium compounds of the water and the alkali of the silicate, the latter going into solution as harmless alkali compounds while lime and magnesia remain in the zeolite. After a sufficient period of use the exchange silicate is revived by treatment with a solution of common salt ( $NaCl$ ); sodium now enters the silicate, while calcium and magnesium are given up to the salt solution as chlorides. The inventor finds that if these igneous rocks (such as trass) be pulverized and boiled with 10 per cent hydrochloric acid, a certain portion of these complex exchange silicates goes into solution. After filtering and washing, the residue is boiled for several hours in a ten per cent solution of alkaline carbonate, to which a small amount of caustic soda has been added. This extract is then mixed with the acid solution, the gelatinous precipitate filter-pressed, and the cake dried at about 70 deg. C. On throwing this cake into water it breaks up into hard, angular grains, which after centrifuging, are found to contain the "exchange" properties of the original trass in a very marked degree. (Assigned to the Permutit Co., 1,263,706; Apr. 23, 1918.) Lemberg pointed out in 1876 that gelatinous exchange bodies could be produced from solutions of alkaline aluminates and alkaline silicates. Previous attempts to convert this gelatinous mass into clinker-like, strong and pervious substances have failed because the precipitate always contained a considerable excess quantity of alkaline mother liquor. The present inventor finds that it is only necessary to mix two solutions of two hydroxides of more or less amphoteric properties together, one such solution being alkaline in reaction and the other being neutral or acid. The word neutral means containing an amount of acid component chemically equivalent to the metal functioning as a base, such, for instance, as aluminium sulphate. As a particular case, if a solution of aluminium sulphate is mixed with a solution of commercial water glass in such proportions that the final mixture shall be neutral to phenolphthalein, a precipitate appears. If this precipitate is filter pressed, dried and granulated as above, it will be found to have "exchange" properties. (Assigned to Permutit Co., 1,263,707; Apr. 23, 1918.)

**Apparatus for Manufacturing Chlormethane.**—Patents No. 1,111,842 and 1,190,659 cover the method of mixing chlorine with a large excess of methane in the cold and then passing the mixture into a heated reaction vessel. Two objects are then attained, namely, a smooth reaction free from carbonization, and a product which consists chiefly of monochlormethane. The chlorination vessel if made of silica or brick is hard to make tight, while on the other hand, most metals are attacked by hot chlorine or catalyze the reaction

The inventor has therefore devised a furnace shown in Fig. 2 consisting essentially of a tight iron tank 1 lined with silica brick 2, with a packing of powdered flint 3 between the two. The cold chlorine entering through pipe 16 is mixed with about five times its volume of cold methane coming through valve 20 in the tee 15. Ten volumes of methane are heated in furnace 17 to about 370 deg. C., and the two gas

streams unite in the silica tube 9 and enter the reaction chamber at a temperature of about 250 deg. C. The reaction

together with a small amount of the reaction

goes forward smoothly without the production of carbon and hydrochloric acid until the gases issuing through 22 contain less than 0.01 per cent of uncombined chlorine. The temperature of the chamber is maintained by the heat evolved by the chemical reaction itself to a temperature of from 400 to 500

FIG. 2

deg. C., and it is only necessary to heat the external iron shell 1 sufficiently that excessive radiation may not cool the contents. Any chlorine gas which percolates outward is changed to hydrochloric acid by contact with the powdered flint before reaching the shell, and consequently rendered incapable of corroding the steel. If pure chlorine enters hot methane as through pipe 12 a chlorine flame produces carbon black and hydrochloric acid only. Dilution as above noted is necessary and the temperature control is very easily had by merely regulating the amount of methane bypassing the furnace 17. (Assigned to Roessler & Hasslacher Chemical Co., 1,263,906; Apr. 23, 1918).

**Side Blown Converter Process.**—JOHN H. HALL, of New York City, (assigned to Taylor-Wharton Iron and Steel Co.), notes that in blowing metal containing say 2 per cent silicon and 0.5 per cent manganese in a side blown converter, the blast impinging on the surface layers will oxidize the various impurities in what amounts to a thin layer of metal. The silicon and manganese oxides form a slag which absorbs iron oxide until the slag becomes freely fluid, and at the same time the iron oxide contained makes it highly oxidizing. This fluid slag is stirred into the carburized

metal remaining in the lower part of the bath by the air currents, when a violent reaction liberating large quantities of carbon monoxide causes a boiling action to froth the metal and slag up so as to overflow the mouth. After subsidence, the slag is stiff and low in iron oxide, and the cycle starts again. In case the manganese is contained in the metal in a greater relative percentage, the time between boils is correspondingly diminished. The patentee claims the process of making slags as high in manganese (approximately of a composition  $\text{SiO}_2$ , 40% and  $\text{MnO}$  60%) that it produces a freely fluid slag from the first and during the greater part of the operation. This slag does not absorb iron oxide as does another lower in manganese, and any iron oxide formed by the blast is then immediately available as an oxygen carrier to the metalloids, which are thereby eliminated gradually without frothing. The requisite proportions of silicon and manganese are had by melting proper pig irons, scrap steels and ferroalloys in the cupola. (1,249,075; Dec. 4, 1917.)

**Acetyl Cellulose.**—WM. G. LINDSAY, of Newark, N. J., received a patent for a method of producing acetylation of cellulose in varied degrees, in which cellulose fibers are saturated with acetic acid and alcohol, then subjected to dehydrating agents—acetic anhydride, sulphuric acid, benzene, etc.—the resulting fibers being physically unaltered and soluble in acetylene tetrachloride. (1,265,216; May 7, 1918.)

**Alunite from Potash Recovery.**—HOWARD F. CHAPPELL, of New York, N. Y., patents the method of converting the alkali in insoluble alumina of calcined alunite into water-soluble compounds, which comprises washing and filtering the calcined alunite to remove soluble potassium compounds, mixing the filter cake with an alkali and an alkali earth, calcining the mixture at about 900 deg. C., and leaching the water-soluble compounds from the calcine. (1,270,266. June 25, '18.)

**Bauxite.**—WALTER L. MELICK, of Columbus, Ohio, patents the process of heating to its boiling point a mixture of substantially saturated aqueous solution of sodium hydroxide and bauxite ground to a degree of fineness of at least seventy mesh, the mixture having the consistency of a thick paste, adding water frequently to prevent drying out, and finally leaching the sodium aluminate formed (1,271,192. July 2, 1918).

**Rust Prevention.**—WM. H. ALLEN, of Detroit, Mich., notes that when articles of iron or steel are treated with soluble acid phosphates according to the patents to Coslett, No. 870,937, and to Richards, No. 1,069,903, they sometimes rust in very small spots. This is possibly due to the formation of hydrates or other compounds capable of causing rusting. He patents the process of rendering these undesirable compounds of iron inactive by placing the treated article for a short time in an approximately five per cent solution of alkali ferrocyanide. By this treatment the deleterious iron compounds are probably changed to mixtures of ferri and ferrocyanides, which are non-corrodible. (1,260,740; Mar. 26, 1918.)

**Purifying Iron in a Blast Furnace.**—GUSTAV R. GEHRANDT, of Oak Park, Ill., patents the process of

purifying the iron produced in a blast furnace by installing a lower row of tuyeres inclined downwardly and so placed that they deliver a stream of hot air into the metal bath, as shown in Fig. 3. The inventor claims that in this way a purified iron is produced; at the same time a saving in fuel is effected owing to the heat abstracted from the molten metal and that fur-

FIG. 3

nished by the purification reactions. The principal agitation is confined to the center of the hearth, leaving a comparatively placid annulus near the walls from which the slag can be drawn without interrupting the refining process. (1,260,660; Mar. 26, 1918.)

**Sponge Iron.**—ALF SINDING-LARSEN, of Norway, patents a process of manufacturing iron sponge from ore wherein the ore is spread in a thin layer over a perforated plate. Heat from an electric resistor is radiated from above through an atmosphere of hydrogen-carrying gas. The water vapor formed by the reaction diffuses quickly, by reason of a great difference in partial pressure, through the ore bed and perforated plate into a lower channel where it is condensed on cooling pipes. In this manner the reduction is more complete, since reoxidation of the iron by moisture is prevented. The ore bed may be carried on a car, whose reciprocating motion works the charge forward with the aid of rabbles fixed in the furnace roof. (1,256,939; Feb. 19, 1918.)

**Annealing Atmosphere.**—FRANK PERRY, of Tipton, England, notes the fact that producer gas used as an atmosphere to prevent scaling or filmlike deposits on metal surfaces during annealing is usually treated in some manner to remove the contained water vapor, unsaturated hydrocarbons, and sulphur compounds. This is not sufficient to prevent all action on bright surfaces, in which case he patents the method of removing saturated hydrocarbons (methane, etc.) by passing the cleaned gas through a tube at 250 deg. C.

containing loose pieces of iron, renewed periodically. (1,261,606; April 2, 1918.)

#### REFRACTORIES

HARRY A. KENNEDY of Clearfield, Pa., proposes to increase the refractivity of silica bricks by carefully screening out and discarding all fine particles of silica before mixing with the finely ground binder of fire clay. In this manner the formation of somewhat fusible silicates between the finely divided and mixed particles of clay and silica is prevented. Bricks subjected to no abrasion can be made of large-sized silica with a minimum amount of binder, while in other cases the expansion of the silica may balance the shrinkage of the clay so as to form a brick of approximately zero temperature coefficient. (1,260,398; Mar. 26, 1918.)

PAUL R. HERSHMAN, of Chicago, has previously patented (No. 1,135,182) the production of refractories capable of withstanding a temperature in excess of 2200 deg. C. These he formed by the use of alumina (preferably from calcined alunite) bonded with carbonaceous material such as glue, hard pitch, and glue-like "tank water" from abattoirs. In heating these pressed refractories he found that they tended to disintegrate during the temperature interval above the decomposition point of the carbonaceous material and below the sintering temperature of the aggregate. He therefore patents the use of a binder such as calcium sulphite which will form compounds holding the mass coherent during this interval, but on further intense heating will be volatilized and thus have no effect upon the ultimate refractivity of the brick. (1,240,569; Assigned to Mineral Products Co., Sept. 18, 1917.)

**Manufacture of Spiegel.**—A. L. CROMLISH, of Sharon, Pa., patents the process of smelting "flush" or "tapping" cinder produced in the open hearth process into a low-manganese, high-phosphorus spiegel which can then be used as a ladle or furnace addition when making steel for subsequent rolling into thin sheets, which steel, as is known, requires a slight addition of phosphorus to prevent sticking when rolling packs of fours and eights in the finishing passes. (1,261,907; Apr. 9, 1918.)

**Ferro Phosphorus.**—H. A. WEBSTER, of Columbia, Tenn., finds that if a proper mixture of iron phosphate, coke and limestone is heated to from 1000 to 1500 deg. C. in a rotary kiln, the interior of the furnace becomes lined with incandescent carbon, which materially hastens the reaction. The products of the reaction—an iron phosphide containing 22 to 25 per cent phosphorus, and a slag—may be granulated and separated by a magnetic separator. The gasified phosphorus may be largely retained in the modular phosphide by charging iron filings or iron ore with the mixture. (1,264,237; April 30, 1918.) The proportion of phosphorus in the compound may be increased to 28 or 30 per cent by heating the above mixture in a closed furnace at two to three atmospheres, cooling the melt under pressure until just molten, and then tapping the contents. (1,264,236; April 30, 1918.)

## Northrup-Ajax High-Frequency Induction Furnace

THE induction furnace described herewith presents features in furnace practice which are radically new in every particular.

All types of induction furnaces heretofore made consist essentially of a step-down transformer. The primary winding of this transformer has many turns on an iron core, and is designed for direct connection to a source of alternating current supply of ordinary or very low frequency. The secondary of this transformer is a closed loop of one turn. The heat developed by the large current which circulates in this single turn is the heat which is utilized. This single turn, usually of molten metal in a trough of refractory material, constitutes a closed electric circuit through which the iron core of the transformer threads.

By employing current of high frequency it becomes unnecessary to use any iron, interlinking with the primary winding and the secondary electric circuit, to obtain the powerful inductive effects which are required to produce efficient heating. The frequency found desirable to use for obtaining good efficiency in the heating is about 20,000 cycles per second. The successful operation of the Northrup-Ajax high-frequency induction furnace is not dependent upon any particular source of supply of this necessary high-frequency current. It has been found most convenient and satisfactory in the construction of furnaces under 100 kw. capacity to use as a source of high frequency current the oscillatory discharge of a bank of condensers.

By properly proportioning the capacity and inductances of the oscillatory current circuits the desired frequency is obtained.

While this type of furnace is perfectly adapted to operation on polyphase circuits with balanced load on the different phases, the particular furnace here described is constructed to operate on single phase only or on one phase of a polyphase supply. The electrical circuits employed for single phase operation appear in Fig. 1.

The line current may be supplied at 110, 220, or 440 volts and 60 cycles. A transformer  $Tr$  steps this e.m.f. up to about 8000 volts. A bank of condensers  $C$  is charged at this voltage and upon rupture of the gap  $G$  oscillations occur.

The current with free high-frequency oscillations passes through an "inductor" coil  $F$  which surrounds the crucible or mass  $M$  to be heated.

This inductor coil has from 50 to 80 turns only and yet its inductive effect is so powerful that currents of great magnitude are induced in the crucible walls, if this is conducting, or in the mass of conducting ma-

terial held in the crucible, if the crucible is non-conducting. The mass  $M$  heats with great rapidity, the inductor coil itself remaining practically cool. A small quantity only of heat-insulating material surrounding

FIG. 2—DISCHARGE GAP

the crucible is required to retain the heat developed. As this heat is developed within the mass to be heated and is not absorbed from an outside supply of heat, as in the resistance wound furnace, it is possible to obtain very high temperatures. No material other than the crucible and its contents is subjected to a destructive temperature, and consequently this type of furnace never burns out and so becomes inoperative.

A series reactance  $X_c$  with tap-offs permits perfect regulation of the power consumed, and another reactance  $X_s$  connected in shunt to the line on the primary side of the transformer serves to adjust the power-factor of the line to be practically unity. If power is supplied from a source of lagging current,  $X_s$  can be so chosen as to improve the power factor.

FIG. 3—INTERIOR VIEW OF DISCHARGE GAP

The power which the furnace will absorb from the source of supply is exactly proportional to the number of condenser units used in the bank of condensers which go to make up the capacity  $C$ . Calculation and experiments show that for the size of unit adopted, which is in over all dimensions 12 x 16 x 13 in. and in capacity 0.07 m.f., 1.5 kw. p.r unit can easily be obtained. Thus a

bank of 16 condenser units is required for a 20 kw. furnace outfit. Of the power supplied at the main switch terminals not less than 50 to 60 per cent makes its appearance as heat in the crucible and contents, being heated by induction.

The discharge gap is also of a radically new type. It has no moving parts and consists essentially of two graphite electrodes (three for two-phase or three-phase operation) opposed to a level surface of mercury. The mercury is contained in a cast-iron pot. The level of the mercury is made adjustable by means provided for lowering and raising an outside reservoir of mercury. The electrodes with graphite tips project through the tightly closed cover. As the discharge takes place in a tightly closed chamber, the noise from the discharge is slight and not at

FIG. 4.—OSCILLATORY CURRENT SYSTEM ASSEMBLY

all objectionable. This gap is found to operate better and the surface of the mercury remains clean if alcohol is slowly dropped into the chamber at about 15 drops a minute.

In Fig. 2 is shown a reproduction of a photograph of a mercury discharge gap with alcohol dropper and mercury regulator. In Fig. 3 is shown a gap with its cover raised to expose to view the electrodes (only two of which are used in single phase operation).

In Fig. 4 is shown a photographic reproduction of a 20-kw. oscillatory current system. It consists of a bank of 16 condenser units and a discharge gap.

Fig. 5 is a photographic reproduction of an oscillatory current furnace of the vacuum type. The practical results obtainable with this new type of induction furnace are numerous and important:

(a) Temperatures exceeding 1600 deg. C. are readily obtained.

(b) Most all nonferrous metals are readily fused without contamination of any kind. The fusion can be made in air or in any desired atmosphere or in vacuum.

(c) Pure iron and pure nickel are readily fused free from contact with carbon.

(d) A nonconductor, as enamel or a high melting glass, is readily fused. Porcelain samples and clays can be studied at temperatures used in firing.

(e) A bath of molten tin, lead or any salt may be uniformly heated and the temperature controlled so that it may be used for heating steel for hardening.

(f) The furnace can be varied in size and form to adapt it to any special requirements. It may be of horizontal, of vertical cylindrical type, or of the muffle type.

(g) A uniform high temperature, up to 1600 deg. C. or more, with a 16-condenser unit outfit, may be main-

tained throughout the volume of a cylinder 6 in. in diameter and 12 in. long, for any kind of heat treatment, such as the heating of iron or steel to be forged. This temperature may be obtained in less than 40 minutes starting cold.

(h) The furnace is admirably adapted to the making of almost all kinds of alloys. The separate constituents can all be heated up from the cold and the alloy allowed to solidify without cracking the container, and if desired may again be heated to fusion without injuring the container. This furnace was invented and developed by Dr. E. F. Northrup for the Ajax Metal Company of Philadelphia. It is manufactured and sold by the Pyroelectric Instrument Co., Trenton, New Jersey. An illustrated 20-page circular describing this furnace has been recently prepared for distribution.

FIG. 5.—STANDARD VACUUM TYPE OF FURNACE

## Hydraulic Operation of Furnace Doors

THE operation of heavy doors, such as are used on open-hearth and heating furnace work, is usually accomplished by the use of hydraulic systems, consisting of pumps, pressure tanks, high pressure pipes, three-way valve, etc. On account of the fact that doors must go up when wanted to go, and vice versa, and due also to the fact that water under pressure has been reliable in the past, the hydraulic system has almost universally been adopted. This is also proof of the fact that no fool-proof, absolutely dependable electric control has ever been worked out before for open-hearth work. A few electric attachments have been made, but they resulted in failure.

The Alan Wood Iron & Steel Co., Conshohocken, Pa., have had in use for thirteen or fourteen months, five hoists with an automatic release, invented by one of their men and manufactured by the Link-Belt Company. These hoists have been in continuous and regular operation without any repairs, attention, or maintenance expense whatever. The illustration shows each hoist provided with a pair of chain sheaves, mounted loose on a worm wheel shaft, between two flanges which are pinned to the shaft and supplied with fiber friction surfaces on the sides toward the sheaves. The worm wheel is driven by a worm mounted on the shaft of a reversible motor, the worm and wheel being enclosed in suitable housing.

To the left-hand sheave is attached a chain which leads up to the tackle for raising the furnace door, and to the right-hand sheave is fastened a chain from which

is suspended a heavy counterweight (down behind the mechanism shown). The wrap of the chains around the sheaves is in opposite directions. The contact surfaces between the sheaves have a beveled, or spiral shape, with the result that when both chains are under tension, the sheaves are squeezed tightly against the friction flanges at the sides, and thus compelled to rotate in the direction of motion of the worm wheel shaft.

To raise the furnace door, the motor is started in the direction which will pull down on the left-hand chain. As long as the counterweight continues its pull, the sheaves squeeze out against the flanges, and are thereby driven in the direction which will wind up the left-hand chain, and thus lift the door. The right-hand sheave has a fixed stop on its periphery, so located that it will come in contact with a stop on the bottom casting when the furnace door has reached its proper height. With the motion of the right-hand sheave arrested by this stop, the shaft cannot rotate the left-hand sheave further, because the squeeze between the sheaves and friction flanges is relieved. There is no opportunity, therefore, for over-winding, and if through carelessness

THE LEWIS HYDRAULIC HOIST

the current is not shut off promptly, the shaft with its flanges will simply continue to revolve in sliding frictional contact with the sheaves, but without power to grip and rotate them further.

For lowering the doors, the direction of the motor is reversed, and practically the same process repeated, except that in this case the power of the motor is used to lift the counterweight, while the pull from the weight of the door serves to keep the sheaves squeezed apart against the friction flanges, until a stop on the left-hand sheave engages with a stop on the bottom casting, and prevents over-winding of the counterweight chain in the same manner as described for the other sheave. In other words, the door always goes up to the proper position, and always comes down to the proper position, no matter what its weight may be. Even if the door were considerably heavier than the counterweight, there would be no danger of its descending and pulling the counterweight up when the motor is stopped, for the instant the counterweight sheave is started toward reversal, the pull of its chain would squeeze the sheaves apart against the friction flanges, and the two sheaves would thus be put completely under control of the worm wheel shaft again, and the worm wheel is, of course, locked in position by the worm. The stop feature does away with the automatic electric switch devices

which have proved so troublesome for this type of hoist, as well as for skip hoists; and it secures an exact stop for all such hoists, without involving failure from human carelessness or complicated electrical equipment. The motor is started, stopped or reversed by simple push-button mechanism.

In the case of skip hoists, the sheaves of course, would be replaced by drums. Doubtless various other applications of the device will suggest themselves; and the fact that it is entirely fool-proof will be appreciated as a great advantage.

### Developments in Grading Solids

STARTING with information drawn from hand sieving, engineers developed an enlargement of this apparatus and called it a shaking screen. All sorts of mechanical motions were applied—eccentrics, toggles and rotators—all being highly successful except for the clogging of the finer meshes. Screen cylinders were developed and somewhat improved by hexagon and octagon forms, but still the milled material tended to accumulate and clog the wires.

Finally the inclined screen with tightly strung wires to which vibrating knockers were applied was evolved. Several advantages were to be had in this form of appliance. Several sizes can be graded at one time; the operation is continuous and regular; the coarser meshed screens, being on top, protect the finer and more delicate ones beneath. The size of the product varies with the cosine of the angles of the incline—200 mesh material is obtained on a 100 mesh weave when the slope is 60 degrees—so that heavier screens can be used for any given work. This gives greater wearing properties besides permitting greater vibrations. Moreover, clogging never takes place.

Of this type of appliance, the new Super Newaygo, manufactured by the Sturtevant Mill Co., Harrison Square, Boston, Mass., is very substantially built and designed for unit construction so any capacity desired can be assembled. All the parts are instantly accessible and can be quickly repaired by replacements when necessary. The coarse screen acts as a scalper and is located in the cover, which is so counterweighted that it can be raised with one hand, leaving the finer screen fabrics accessible. Very efficient knockers apply sufficient vibration to keep the mesh wires clear.

### Licensing of Engineers

At the regular meeting of Engineering Council June 20, a special report by the Public Affairs Committee on the Licensing of Engineers, was debated at length. It was decided to create a small Special Committee, with very carefully selected membership, to study this important question thoroughly with a country-wide view. It is intended that through the work of this committee, Engineering Council shall in due time be prepared to advise engineering organizations in any of the states upon this much discussed matter. Engineers who have knowledge of proposed legislation are requested to communicate with the Secretary of Engineering Council. Information or rumor has already been received of possible action by the Legislatures of Iowa, Ohio, Indiana and Michigan. As is well known, a few states have passed laws.

## Book Reviews

**THE HISTORY OF CHEMISTRY**, by Prof. T. S. Moore. 240 pages. Price, \$2.50. New York: McGraw-Hill Book Co., Inc.

According to Dr. George Sarton, erstwhile of the University of Ghent, the history of science is the history of man's conquest over nature. In this respect only has man been constantly progressive. In religion, in morals, and in arts, the question of his steady advancement is open to discussion, whereas in science his advancement has been slow but continuous. Therefore, if we would know man as a progressive creature, we must consider him from the angle of vision in which this quality comes into view. If we would make a just estimate of the present from the past and would compute the future in the light of human advancement, we shall need the history of science to enlighten us. The history of science is therefore of value from an ethical standpoint.

And now Professor Moore has given us a textbook on the subject of chemistry. From beginning to end the pinch of space is felt, because the subject is one for a whole library rather than for a single book, and with such wealth of material it was necessary to compress and delete and squeeze until only the high lights are touched upon. And these high lights, like John Mayow, come out of the shadow of the past and flit by so swiftly that the little glimpses we get seem all too short and inadequate. But we are dealing with a textbook on the history of chemistry and it is the business of a textbook to whet the appetite.

Dr. Moore addressed himself to a history of the science rather than a record of the men who made it, and this gives us an excellent short memorandum of its development. Only six pages cover the history of the Greek contributions and but eight pages are devoted to alchemy; then we begin with the Renaissance, with Paracelsus the first chemist.

But even here there are only seven pages to lead us along through the iatro-chemists, from Phillippus Aureolus Paracelsus Theophrastus Boombastus Eremit von Hohenheim, born in 1493, to and including Johann Rudolf Glauber (1604-1668) who sold secret medicinal preparations, including the salt that bears his name. These notes include a memorandum on Agricola who, although a physician, was rather a metallurgist than an iatro-chemist, as is duly pointed out.

At this point we reach a rebirth in chemical philosophy, beginning with Robert Boyle (1627-1691). From the time of the Greeks until Boyle's day, it would seem that whatever there was to chemistry had been kept outside of the pale of distinguished scholarship. The alchemists worked in secret and their ideals were not such as to attract men of character. Albertus Magnus and Roger Bacon seem to have been men of vision, although the usual alchemistic purpose was to get rich quick by a clever trick. To devote a life to finding how this may be done has never appealed to the best quality of men.

Robert Boyle was a gentleman by birth, training, education and character, and his advent gave the signal for high thinking, open-mindedness and frankness. By the very merit of his work he put the quack doctors where they belonged without the trouble of quarreling with them. He did it very simply—by outclassing them. When we look up we look for the top and when men of his day looked toward the top in chemistry they found a gentleman and a scholar instead of an itinerant quack doctor with secrets to sell. Then chemistry began to grow and, in spite of Stahl's unfortunate injection of phlogiston into the subject, Boyle had set the pace.

Dr. Moore gives a photograph of a page of Stahl's "Fundamenta Chemicæ," which was begun in Latin but finished in German. The page in question is from the middle of the book and we shall give only part of a sentence to show his style. It is no wonder that a man who wrote like this should confuse chemistry! "Denn es gehen in dieser Dissolution des nitri, idem sich die Mixtur entzündet, variae portiones in forma flammæ weg, und machen einen

Rauch welche eine kuenstlich, applicato scil. super crucibulum recibulum recipiente fangen; nemlich sie thun diese Mixtur in ein gluehend Geschirr . . . und der Dunst . . . wird gefangen, da er sich in einen Liquorem condensirt, qui vero plane alienus est a Spiritu nitri iridole. . . ."

The book proceeds rapidly over the thorny road of phlogiston, giving, in carefully arranged sequence, what was thought by men who have made leading contributions to chemistry on the subject in hand. The problem of the author required that this be done and limitations of space doubtless required that only the merest reference be made to the personality of most of these men. This is the criticism we have to make and we do so without blaming the author or the publishers. A textbook must be compact. It is richly illustrated, chiefly by means of portraits of great men, but we would prefer their biographies to their likenesses.

There are two methods of teaching history. One is the method selected by the author to give a history of the subject and to mention the leaders as incidents in its development. This is the short and compact method. The other is to provide a more general record of progress and then to confirm the steps by giving biographical sketches of the leaders, including such personal details concerning them as will confirm them in memory. This takes more time and is less orderly, but it has its advantages. It humanizes the subject and that makes it more likely to be remembered. There is in this book a delightful little sketch of John Dalton written by himself which shows him as a school teacher at twelve years of age, and there is also a living and sincerely appreciative picture of Liebig, which is very charitable withal. Of Berzelius we should like to know more, although he is recorded as the organizer of the science. It is, on the whole, a scholarly work and, so far as we have been able to observe, it is unusually free from error.

## Personal

MR. PHILIP R. BRADLEY, of Treadwell, has been appointed Food Administrator for Alaska.

MR. HENRY CASE, until recently director of technical research with the David-Bournonville Co., Jersey City, N. J., has assumed the duties of production manager of the S. K. F. Ball Bearing Co., Hartford, Conn.

MR. L. G. EAKINS, for years general manager of the Colorado branch of the American Smelting and Refining Company, has resigned his post in Denver and will move to New York City as consulting metallurgist for the smelting corporation. He will be succeeded in Denver by C. A. H. DeSaules, who has held an important place with the company in New York City. In New York Mr. Eakins will be located at 120 Broadway.

MR. JAMES H. HUGHES has been appointed manager of the steel and tube department of the Timken Roller Bearing Company at Canton, Ohio, effective July 1. He was formerly with the Carnegie Steel Company, having spent fourteen years in that organization.

MR. J. W. HUTCHINSON, former manager of Goldfield Consolidated Mines Co., has resigned to join the Army. He is succeeded by E. A. Julian, former chief engineer of the Wingfield interests.

MR. G. J. KAPTEYN, a Dutch engineer widely known and traveled in metallurgical and mining districts in both Americas, has passed through the United States en route to the East Indies on Dutch government business.

MR. A. D. LEDOUX has been appointed chairman of the Chemical Alliance Committee on the Production, Distribution and Control of Sulphur Materials. His associates are W. D. Huntington and C. G. Wilson. Headquarters are at Room 135, Interior Building, Washington, D. C., or 15 William St., New York City.

MR. H. J. MORGAN, of the General Chemical Company, has been transferred from the Delaware Works at Marcus

Hook, Pa., to the main laboratories of the company at Laurel Hill, Long Island, where he will be chemist in charge.

PROF. C. W. PARMELEE, of the department of ceramic engineering, University of Illinois, Urbana, Ill., is making a survey of the ball-clay deposits of West Tennessee.

MR. JOEL H. WATKINS, formerly economic geologist for the Southern Railway System, has opened an office at Room 1364, 200 Fifth Avenue, New York. He intends to devote special attention to the mineral resources of the Appalachian South.

DR. THEODORE W. RICHARDS, Erving professor of chemistry and director of the Wolcott Gibbs Memorial Laboratory at Harvard University, has been made a foreign member of the Accademia dei Lincei, Rome. He has been elected an honorary member of the Royal Irish Academy.

MR. H. E. SHIVER, assistant chemist, South Carolina Experiment Station, Clemson College, S. C., and formerly a member of the United States Army Flying Corps at Princeton University, has accepted a position as chemical engineer with the Air Nitrates Corporation at their electrochemical plant at Muscle Shoals, Ala. He will be in a supervisory position in unit 5 of the plant.

MR. ARTHUR H. YOUNG, director of the American Museum of Safety since January 1, 1917, has resigned to take charge of the Employee Relations Department of the International Harvester Company. He will take up his new duties immediately but will continue to be closely concerned with museum affairs, as he has been elected to the vice presidency, succeeding the late Dr. Frederic R. Hutton.

Obituary

PROFESSOR STEPHEN FARNUM PECKHAM, chemist and authority on bitumens, died at his residence at Brooklyn on July 11, at the age of seventy-nine. Professor Peckham was born at Fruit Hill, Providence, R. I., and was educated at the Friends School and at Brown University. From 1869 to 1873 he taught chemistry at Washington College. Later he held the chair of chemistry at Maine State College and at the University of Minnesota. He was also chemist to the Minnesota Geological Survey and the State Board of Health.

From 1898 to 1911, he conducted a laboratory for the Commissioners of Accounts and later for the Finance Department of New York. He contributed scientific articles to the Encyclopedia Britannica, the American Encyclopedia and Chemical News, and wrote a treatise on asphalt. Nine years ago, he suffered a stroke of paralysis, which ultimately caused his death. His wife, two daughters and a son survive him.

Current Market Reports

Non-Ferrous Metal Market

Thursday, July 25.—With strong demand and higher labor costs, prices still tend to increase except where fixed by regulations.

Aluminium.—The government price on ingots is 33c. a pound f.o.b. plant in 50-ton lots, 33.1c. down to 15-ton lots, and 23.2c. in lots down to 1 ton, and 40 to 45c. for smaller lots; sheet aluminium, 18 ga. and heavier, 42c.; and powdered aluminium, \$0.65 to \$3.00 per lb. according to mesh.

Antimony.—The demand is developing and spot duty paid has advanced to 13 1/4 to 13 1/2 c.

Chrome.—Producers have established a schedule on the basis of \$1.30 per unit ore; some 40% ore has been sold at a premium at \$1.50 per unit.

Copper.—Government price fixed at 26c. until August 15. Copper products are quoted at:

|                            |        |   |            |
|----------------------------|--------|---|------------|
| Copper sheets, hot rolled  | \$0.36 | — | \$0.37 1/2 |
| Copper sheets, cold rolled | .37    | — | .38 1/2    |
| Copper bottoms             | .44    | — | .45 1/2    |
| Copper rods                | .36    | — | .37        |

|                        |         |           |
|------------------------|---------|-----------|
| Copper wire            | .29 1/2 |           |
| High brass wire        | .28 1/2 | — .29 1/2 |
| High brass sheets      | .28 1/2 | — .29 1/2 |
| High brass rods        | .28 1/2 | — .29 1/2 |
| Low brass wire         | .32 1/2 | — .34 1/2 |
| Low brass sheets       | .32 1/2 | — .34 1/2 |
| Low brass rods         | .34 1/2 | — .35 1/2 |
| Brazed brass tubing    | .37     | — .39     |
| Brazed bronze tubing   | .42 1/2 | — .44 1/2 |
| Seamless copper tubing | .41     | — .43     |
| Seamless bronze tubing | .45     | — .46     |
| Seamless brass tubing  | .37 1/2 | — .39 1/2 |
| Bronze (gold) powder   | 1.00    | — 1.75    |

Lead.—Metal scarce for spot delivery. Price in New York 8.05c. per lb., in East St. Louis 7.75c. in 60,000-lb. lots; full lead sheets, 10c., cut sheets 10 1/4 c.

Manganese.—Such lots of manganese ore as reach New York are quickly taken at \$1.35 basis.

Molybdenum.—Quoted at \$1.25 per pound MoS<sub>2</sub> for 90 per cent material. There is considerable inquiry from abroad, but it is not known whether exportation will be permitted.

Spelter.—Bids are at 8.6c., while 8.75c. is asked. East St. Louis settling price is 8.40c. in 60,000-lb. car lots. Sheet zinc is 15c. and zinc dust 18 to 20c. per pound.

Tin.—Imports for the first three weeks of this month have been 5000 tons. Banca tin spot delivery for Government work has brought \$1.00 per pound, futures at 90 to 95c. Chinese tin for August shipment is quoted around 91c. Babbitt metal varies between \$1.10 and 70c. per pound. Solder 50-50, 73c.

Tungsten.—The highest grade material containing no tin, no copper and low manganese and over 70 per cent WO<sub>3</sub> is very scarce. Ore with slight impurities is bringing \$23.50 per unit, lowest grades down to \$18 per unit.

OTHER METALS

|           |        |                 |
|-----------|--------|-----------------|
| Bismuth   | lb.    | \$3.50          |
| Cadmium   | lb.    | 1.50            |
| Cobalt    | lb.    | 2.50 — \$3.50   |
| Magnesium | lb.    | 1.75 — 2.00     |
| Mercury   | 75 lb. | 125.00 — 130.00 |
| Nickel    | lb.    | 40.00 — 45.00   |
| Iridium   | oz.    | 175.00          |
| Palladium | oz.    | 135.00          |
| Platinum  | oz.    | 105.00          |
| Silver    | oz.    | .99 1/2         |

The Iron and Steel Market

While much of the discussion relating to supplies and requirements in steel relates to the demand that is not accorded any form of precedence by the controlling authorities and to the supplies that may be left for such purposes after the preferences, etc., are met, the fact is that by far the most important matter in steel distribution is the distribution under the priorities and preferences. Steel producers quite familiar with the situation continue to estimate that the demand accorded no form of precedence does not amount to 10 per cent of the total demand, and thus it is relatively unimportant when the 90 per cent or more is very far from being fully taken care of.

The trade has become familiar with the new nomenclature and regulations prescribed by the War Industries Board's statement dated July 3 and subsequently circulated to the trade. The sequence in which wants are to be taken care of is as follows: Priorities, AA, A and B, respectively, with certain subnumbers; Preferences, or Class C; Class D, or all other.

The priorities are precise orders, requiring a producer to furnish a consumer a specified quantity of material. It is not necessary that all priority orders be actually filled before any material is shipped under preferences, but merely that they shall be "provided for," i.e., the producer must be assured that the manufacturing facilities are set aside to the extent necessary to make the shipment in good time.

The preference list, while given as an appendix in the statement of July 3, is substantially the list originally promulgated under date of June 6. It prescribes the sequence of importance, and runs from direct war purposes through to peace or commercial purposes of the more important character, the purposes being in brief: Ships, aircraft, munitions, fuel, food, clothing, railroad, public utilities. All these classes, it is now clearly understood, are to be interpreted broadly. Food, for instance, covers everything in the production and preparation of food, even to the

production of cook-stoves and cooking utensils for the household, though there is an order of sequence here also, and the public is expected to get along with as few new cook-stoves as possible. The mills are expected to use their judgment in these matters, referring doubtful cases to Washington.

The Class D material is subject to production and shipment only by written permit of the Director of Steel Supply, except that shipments up to five tons are covered by a blanket permit, subject to the restriction that the producer must report all such shipments monthly and certify a belief that they were "in the public interest."

The jobbers are placed under the same restrictions as the producers in the matter of making shipments. They are required to report shipments and are to be given replacement of material against approved shipments. They are, however, required to endeavor to get along with as light stocks as possible and are expected to influence retail dealers to do the same.

#### NOT ENOUGH STEEL

With the amount of priority business on books and the government's demand for material under the preference list, there is far from enough steel to reach fully over the commercial purposes that are covered by the preference list. There is a divergence of opinion whether the more direct war needs are really of sufficient volume to require that the tail end of the preference list be ignored to a great extent. The War Industries Board holds that there is not nearly enough steel production in prospect to meet all requirements, while many in the steel industry maintain that the war activities will not be able, during the next few months, to consume steel as rapidly as they are calling for it.

The discussion centers largely around a recent statement of the War Industries Board, that the requirements for the second half of the year total about 21,000,000 net tons, while the steel industry has never produced more than 16,500,000 net tons in a half year. But little explanation is given of these bare totals. There is no attempt made to indicate how the 21,000,000-ton total is made up, and as to the 16,500,000 tons production, assumed to be net tons, the fact is that in 1916 the production of finished rolled steel was about 34,200,000 net tons. The production in June was at the rate of about 36,000,000 net tons a year, assuming, as seems fair, that finished rolled steel was 75 per cent of the ingot tonnage, indicated by partial reports to have been at the rate of 43,500,000 gross tons a year.

While details have not been made public, it is evident that the 21,000,000-ton estimate must have been made up of material in two categories, first the stated requirements of the various Government activities—shipbuilding, shell manufacture, aircraft production, requirements of our allies, etc.; second, estimates of what the recognized commercial industries will require. From some of these industries estimates may have been received, but it is rather clear that "public utilities" were unable to make precise estimates, if indeed they individually made any at all.

It may be that the Shipping Board has overstated the amount of steel it will be able to use to January 1, 1919, and it may likewise be that it will be so successful in its work as to be able to consume more steel than it now estimates. What is clear is that with everyone trying to produce and consume a maximum it cannot be foretold precisely what will be done. The War Industries Board, therefore, sets a high mark for the steel industry to aim at, and is very conservative in allowing steel to pass to the less important commercial industries.

While according to the estimates are forecasts that there is not to be enough steel, the actual situation is not such by any means. There are many jobbers and manufacturing consumers who insist that they need more steel, but in most cases it is a case of looking into the future. There is, after all, very little if any work of real importance that is being retarded seriously if at all by lack of steel. The shipyards are in many cases accumulating steel and few if any are hampered by lack of steel. The forge shops, making shell blanks, are in the main well supplied and it is rumored that some have uncomfortably large stocks. At the shell factories there seems to be a fairly good supply

of material. The railroads doubtless could use more cars, but their performance is improving each month through better organization.

#### PIG IRON

If there were a normal supply of scrap, in proportion to pig iron, there would probably be no shortage of pig iron, for the requirements of the iron foundry trade in general are quite below normal. The total supply of scrap is insufficient, and the average character of scrap available is much below normal. Accordingly more pig iron is required, and with the increased proportion of pig iron for open-hearth furnaces using the pig and scrap process the ingot output is below the ordinary ratings of capacity. There is, however, no acute shortage of pig iron.

#### Chemical Market

**COAL TAR PRODUCTS:**—The last two weeks' period has been marked by the usual summer quietness although in those items which have shown some activity there have been slight increases in prices quoted. The saccharines have shown a continuing advance with the growing demand and the soluble still holds the preference.

**Phenol:**—Even inquiry has been very quiet for this material and large factors in its production are offering at 44c for material in large quantities on contract. Certain other directions continue to hold at 45c although on resale there is material available at less than either figure. Actual holdings of the English material are at local warehouses but holders state that it is not expected that further importations will be made. These are being offered at 45c, ex store.

**Aniline Salts:**—A very limited supply of this material is available even on the resale market and large manufacturers state that they are all sold up and are quoting 42c per pound. Demand is very good but holders are very hard to locate.

**Saccharine:**—The soluble material continues in favor and in very strong demand. Manufacturers are behind in filling contracts so far back as April and it has become almost impossible to locate holdings in second hands. The last sales reported were at \$32 on the soluble and \$31 on the insoluble.

**Coumarin:**—This product also is at present very short in supply as compared with demand and large interests who are succeeding at all in receiving shipments are doing them out sparingly among their regular customers. Such interests quote general prices of from \$28 to \$30, but as to the resale market in the few instances where actual holdings are known quotations are on the basis of \$32.50.

**Benzoate of Soda:**—The demand for this product has fallen off in the last week until there is practically no call. Purchases can be made at \$2.90 although the general holding is at \$3.00. The acid has assumed a level of from \$3.10 to \$3.25.

**Dimethylaniline:**—Demand is fair for this time but actual holdings are hard to locate. Small quantities are being offered from time to time and the present asking price for such lots is from 75 to 80c.

**Paranitraniline:**—The demand continues very good and new sources of supply are available. Such offerings are made at from \$1.75 to \$1.80.

**Hexamethylenetetramine:**—The demand for this material has fallen off somewhat from the active demand of a week or two ago and prices asked by large producers are now at \$1.05 and \$1.10 depending upon quantity. Large quantities cannot be delivered because of the scarcity of raw materials. Production is also affected by the present labor and transportation conditions and the fact that the government is taking over a large portion of the production.

**Meta Amidophenol:**—Supplies are not very large as the manufacture is for special color purposes and only small advance stocks of material are kept on hand. It is thought that the price of \$6.50 which is quoted in certain directions could be bettered on firm orders.

**HEAVY CHEMICALS:**—Although the market in general has been very quiet caustic soda has shown some little activity. In the case of saccharine a tendency to the returning of the old relations between the soluble and insoluble is evident.

**Bichromate of Soda:**—The majority of stocks are held by very strong houses and there is very little competition. The last sales noted were at 26½¢ and it was thought that 26¼¢ could be done although there are some holders who will not shade 30¢ at the same time admitting that there seem no immediate prospects of receiving this price.

**Caustic Soda:**—Material from store is being quoted at \$3.80 and \$3.90 in several directions but from one source, an export house, it is reported that \$4.25 could not be shaded on a delivered price. Some 2700 tons were recently ordered through the Japanese government for one of the companies operating in Japan under subsidy. Part of this order was shipped in June and the balance was booked for July. The Japanese government arranged for the necessary permits.

**Soda Ash:**—Offers on double bags at Chicago have shown a slight increase as \$3 is last reported to have been paid as against \$2.65 recently. There is very little activity in the local market as bags are held at \$2 store in some quarters although some are quoting \$2.05 and \$2.10. The price on barrels New York continues at about \$2.90 with dense ash at \$3.85 or \$4 f.a.s.

**Bichromate of Potash:**—There has been a slight movement with offers generally made at 43 and 44c, without attracting much buying attention.

**Lead Peroxide:**—It is reported that new manufacturers are entering the field and will produce this material in powdered form on which they are quoting a price of 35¢ per pound and accepting orders for any quantities.

**Calcium Carbide:**—This item has been showing a gradual increase and is expected to reach ultimately the 20c level. The last general quotations for the sizes in greatest demand were at 19c at which the market appears to be very well established.

## General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET, JULY 8, 1918

|                                               |      |               |       |
|-----------------------------------------------|------|---------------|-------|

| Sodium chlorate                                 | lb.     | .13           | .14    |
| Sodium cyanide                                  | lb.     | .17           | .18    |
| Sodium fluoride, commercial                     | lb.     | 2.40          | 2.50   |
| Sodium hyposulphite                             | lb.     | 2.50          |        |
| Sodium molybdate, per lb. of Mo                 | lb.     | Nominal       |        |
| Sodium nitrate, 95 per cent                     | 100 lb. | .28           | .30    |
| Sodium nitrite                                  | lb.     | .35           | .45    |
| Sodium peroxide                                 | lb.     | .04           | .05    |
| Sodium phosphate                                | lb.     | .53           | .55    |
| Sodium prussiate, yellow                        | lb.     | Nominal       |        |
| Sodium silicate, liquid (60 deg.)               | lb.     | Nominal       |        |
| Sodium sulphide, 30 per cent, crystals          | 100 lb. | Nominal       |        |
| Sodium sulphide, 60 per cent, fused             | 100 lb. | Nominal       |        |
| Sodium sulphate, 90-95 per cent                 | ton     | Nominal       |        |
| Strontium nitrate                               | lb.     | .25           | .35    |
| Sulphur, flowers, sublimed                      | lb.     | .06           | .06½   |
| Sulphur chloride, drums                         | lb.     | .23           | .26    |
| Sulphur dioxide, liquid, in cylinders           | 100 lb. | 4.05          | 4.60   |
| Sulphur, flowers, sublimed                      | 100 lb. | 3.70          | 3.85   |
| Sulphur, roll                                   | ton     | Nominal       |        |
| Sulphur, crude                                  | ton     | Nominal       |        |
| Tin bichloride, 50 deg                          | lb.     | 1.00          | .29    |
| Tin oxide                                       | lb.     | .18           | .20    |
| Zinc carbonate                                  | lb.     | .15           | .15½   |
| Zinc chloride                                   | lb.     | Nominal       |        |
| Zinc cyanide                                    | lb.     | .14           | .16    |
| Zinc dust, 350 mesh                             | lb.     | .13           | .14    |
| Zinc oxide, American process XX                 | lb.     | .05           | .06    |
| Zinc sulphate                                   | lb.     | .05           | .06    |

## Coal Tar Products (Crude)

|                                        |      |               |       |
|----------------------------------------|------|---------------|-------|
| Benzol, pure, water white              | gal. | .23           | .26   |
| Benzol, 90 per cent                    | gal. | (Fixed Price) | 1.50  |
| Toluol, for non-military use, in drums | gal. | (Fixed Price) | 1.55  |
| Xylol, pure, water white               | gal. | .45           | .55   |
| Solvent naphtha, water white           | gal. | .12           | .15   |
| Solvent naphtha, crude, heavy          | gal. | .40           | .55   |
| Cresote oil, 25 per cent               | gal. | .30           | .32   |
| Dip oil, 20 per cent                   | gal. | .80           | 1.00  |
| Pitch, various grades                  | ton  | 1.05          | 20.00 |
| Carbolic acid, crude, 95-97 per cent   | lb.  | .60           | .65   |
| Carbolic acid, crude, 50 per cent      | lb.  | .35           | .38   |
| Carbolic acid, crude, 25 per cent      | lb.  | .18           | .20   |
| Cresol, U. S. P.                       | lb.  | .35           |       |

## Intermediates, Etc.

|                              |     |         |       |
|------------------------------|-----|---------|-------|
| Alpha naphthol, crude        | lb. | 1.00    | 1.10  |
| Alpha naphthol, distilled    | lb. | 1.60    | 1.70  |
| Alpha naphthylamine          | lb. | .60     | .65   |
| Aniline oil, drums extra     | lb. | .27     | .28   |
| Aniline salts                | lb. | .37     | .42   |
| Anthracene, 80 per cent      | lb. | Nominal |       |
| Benzaldehyde (f.f.c.)        | lb. | 3.65    |       |
| Benzidine, base              | lb. | 1.75    | 2.00  |
| Benzidine, sulphate          | lb. | 1.40    | 1.50  |
| Benzonic acid, U. S. P.      | lb. | 3.10    | 3.25  |
| Benzoate of Soda, U. S. P.   | lb. | 2.90    | 3.00  |
| Benzyl chloride              | lb. | 2.60    | 2.70  |
| Beta naphthol benzoate       | lb. | 10.00   | 12.00 |
| Beta naphthol, sublimed      | lb. | .85     | .90   |
| Beta naphthylamine, sublimed | lb. | 2.65    |       |
| Diethyl benzal               | lb. | .15     | .20   |
| Diethylaniline               | lb. | 4.50    | 5.00  |
| Dinitro benzol               | lb. | .36     | .38   |
| Dinitrochlorobenzol          | lb. | .40     | .42   |

|                                |     |      |   |      |
|--------------------------------|-----|------|---|------|
| Dinitronaphthalene             | lb. | 55   | — | 60   |
| Dinitrotoluol                  | lb. | 65   | — | 75   |
| Dinitrophenol                  | lb. | 55   | — | 60   |
| Dimethylaniline                | lb. | 75   | — | 80   |
| Diphenylamine                  | lb. | 10   | — | 10   |
| H-acid                         | lb. | 2.70 | — | 3.00 |
| Metaphenylene diamine          | lb. | 1.75 | — | 2.00 |
| Monochlorobenzol               | lb. | 17   | — | 20   |
| Naphthalene, flake             | lb. | 00   | — | 09   |
| Naphthalene, balls             | lb. | 101  | — | 102  |
| Naphthionic acid, crude        | lb. | 1.20 | — | 1.30 |
| Naphthylamin-di-sulphonic acid | lb. | 1.00 | — | 1.20 |
| Nitro naphthaline              | lb. | 45   | — | 50   |
| Nitro toluol                   | lb. | 55   | — | 60   |
| Ortho-amidophenol              | lb. | —    | — | —    |
| Ortho-dichlor-benzol           | lb. | 15   | — | 18   |
| Ortho-toluidine                | lb. | 1.00 | — | 1.25 |
| Ortho-nitro-toluol             | lb. | 75   | — | 1.00 |
| Para-amidophenol, base         | lb. | 4.00 | — | 4.50 |
| Para-amido-phenol, H. Cl.      | lb. | 4.00 | — | 5.00 |
| Para-dichlor-benzol            | lb. | 15   | — | 20   |
| Paranitraniline                | lb. | 1.75 | — | 1.90 |
| Para-nitro-toluol              | lb. | 1.50 | — | 1.60 |
| Paraphenylenediamine (base)    | lb. | 3.75 | — | 4.00 |
| Para-toluidine                 | lb. | 2.00 | — | 2.25 |
| Phthalic acid anhydride        | lb. | 3.50 | — | 4.00 |
| Phenol, U. S. P.               | lb. | 44   | — | 46   |
| Resorcin, technical            | lb. | 5.00 | — | 7.00 |
| Resorcin, pure                 | lb. | 8.00 | — | 9.00 |
| S-sulvic acid                  | lb. | 8.00 | — | 1.10 |
| Salol                          | lb. | 1.50 | — | 2.00 |
| Sulphanilic acid, crude        | lb. | 2.50 | — | 3.2  |
| Tolidin                        | lb. | 2.50 | — | —    |
| Toluidine-mixture              | lb. | 85   | — | 90   |

### Petroleum Oils

#### Crude (at the Wells)

|                       |      |      |   |      |
|-----------------------|------|------|---|------|
| Pennsylvania          | bbl. | 4.00 | — | —    |
| Corning, Ohio         | bbl. | 2.85 | — | —    |
| Somerset, Ky          | bbl. | 2.60 | — | —    |
| Wooster, Ohio         | bbl. | 2.58 | — | —    |
| Indiana               | bbl. | 2.28 | — | —    |
| Illinois              | bbl. | 2.42 | — | —    |
| Oklahoma and Kansas   | bbl. | 2.25 | — | —    |
| Caddo, La., light     | bbl. | 2.25 | — | —    |
| Corcoran, Tex., light | bbl. | 2.35 | — | —    |
| California            | bbl. | 2.20 | — | —    |
| Gulf Coast            | bbl. | 1.35 | — | 1.57 |

#### Fuel Oil

|                |      |      |   |      |
|----------------|------|------|---|------|
| New York       | gal. | .11  | — | —    |
| Pittsburgh     | gal. | .07  | — | 10   |
| Oklahoma-Kans. | bbl. | 1.05 | — | 2.75 |
| Texas          | bbl. | 1.85 | — | 2.35 |
| Los Angeles    | bbl. | 1.60 | — | —    |
| San Francisco  | bbl. | 1.60 | — | —    |

#### Gasoline (Wholesale)

|               |      |      |   |   |
|---------------|------|------|---|---|
| New York      | gal. | .24  | — | — |
| Boston        | gal. | .25  | — | — |
| Pittsburgh    | gal. | .28  | — | — |
| Chicago       | gal. | .224 | — | — |
| Oklahoma      | gal. | .25  | — | — |
| San Francisco | gal. | .20  | — | — |

### Lubricants

|                                              |      |     |   |     |
|----------------------------------------------|------|-----|---|-----|
| Black, reduced, 29 gravity, 25-30 cold test. | gal. | .23 | — | .24 |
| Cylinder, light                              | gal. | .40 | — | .42 |
| Cylinder, dark                               | gal. | .39 | — | .41 |
| Paraffine, high viscosity                    | gal. | .40 | — | .42 |
| Paraffine, 903 sp. gr.                       | gal. | .35 | — | .38 |
| Paraffine, 885 sp. gr.                       | gal. | .25 | — | .27 |

### Flotation Oils

(Prices at New York unless otherwise stated)

|                                                                     |      |     |   |    |
|---------------------------------------------------------------------|------|-----|---|----|
| Pine oil, crude, f. o. b. Florida                                   | gal. | .44 | — | —  |
| Pine oil, steam-distilled, sp. gr. 0.925-0.940                      | gal. | 58  | — | 60 |
| Pine oil, destructively distilled                                   | gal. | 58  | — | 60 |

## Plant Construction—Catalogs—New Publications

### Construction and Operation

#### Arkansas

**HARRISON**—The Harrison Mining & Milling Co., located in Crooked Creek Valley Mining District, will rebuild its 75-ton mill recently destroyed by fire. The company is in the market for sludge and slime tables, belts, mill hardware, mill lumber, and air compressors. Estimated cost, \$18,000. George Constant, Harrison, superintendent.

**MENA**—The Abbott, Rebholz and Stewart Mining Co., Baxter Springs, Kan., will build a concentration plant here. Estimated cost, \$25,000. The company is in the market for steam shovel, crushers, washers, belts, cars, engine and boiler. J. I. Abbott, superintendent.

**MOUNTAIN HOME**—The Mattie May Mining Co. will build a 150-ton concentration plant and is in the market for sludge and slime tables, engines, boilers, crushers, air compressors, lumber, mill hardware, roofing, piping, belts and cables. Estimated cost, \$40,000. E. Zimmerman, superintendent.

**BATESVILLE**—The Vance Mining Co. will build a 100-ton concentration plant and is in the market for steam shovel, cars, track, log washer, lumber, mill hardware, engine and boiler. Estimated cost, \$25,000. C. H. Plumb, Miners Bank Bldg., Joplin, Mo., superintendent.

#### Alabama

**ASHLAND**—The Grisesmer Graphite Co. will rebuild its concentration plant recently destroyed by fire. Estimated cost, \$75,000. F. C. Hooper, Ashland, superintendent.

#### Arizona

**AJO**—The New Cornelia Copper Co. will build a flotation plant for the care of new ore production, and will later build a smelter.

**WALKER**—The Black Diamond Mining & Development Co., Prescott, will build a concentration and flotation mill and install machinery for same. Estimated cost between \$10,000 and \$15,000. J. Irwin, P. O. Box 463, Prescott, superintendent.

#### Connecticut

**NEW HAVEN**—Yale University will build a 5-story, 100 x 100 ft., reinforced concrete, brick and steel laboratory. Estimated cost, \$300,000. Day & Klauder, 925 Chestnut St., Philadelphia, Pa., architects.

**PUTNAM**—The Manhasset Manufacturing Co., 33 Canby St., has awarded the contract for the construction of a 2-story, 40 x 100 ft., concrete and brick factory, for the manufacture of tires, to Torrington Building Co., 19 North St., Torrington. Estimated cost, \$40,000.

#### Illinois

**CHICAGO**—The Symington - Chicago Corporation, 122 South Michigan Ave., has awarded a contract for the construction of a 1- and 2-story brick and steel munition plant on Seventy-fourth and Ashland sts. to Thompson-Starratt Co., 175 West Jackson St. Cost between \$5,000,000 and \$6,000,000.

**HEGEWICH**—The General Chemical Co., 25 Broad St., New York City, has awarded the contract for the construction of a 120 x 140 ft. factory building, to the Austin Co., 16112 Euclid Ave., Cleveland, O.

#### Kansas

**BAXTER SPRINGS**—The Chitto Lead & Zinc Co. will build a 250-ton concentration plant. Estimated cost, \$45,000. The company is in the market for oil engine, lumber, mill hardware, sludge tables, air compressors, belts and crushers. Frank Chitto, Baxter Springs, superintendent.

**BAXTER SPRINGS**—The Cook & McCulloch Mining Co. will build a 150-ton concentration plant, and is in the market for sludge and slime tables, crushers, air

compressors, conveyors, air pipes, belts, jigs, drills, ore cars, track, engines, boilers, lumber, mill hardware and concrete for mill bases. Estimated cost, \$40,000. W. McCulloch, Baxter Springs, superintendent.

**BAXTER SPRINGS**—The Euterpe Mining Co. will remodel its 200-ton concentration plant and is in the market for roofing, lumber, belts, conveyors, hardware, sludge tables, drills and crushers. Estimated cost, \$35,000. C. Clark, superintendent.

**CRESSWELL**—Frank Nicholson and Frank Harrington, 202 Sargent St., Joplin, Mo., will build a 150-ton concentration plant at their mine here, and are in the market for mill machinery, lumber, hardware, oil engine, sludge and slime tables, crushers, ore cars, ore bins and air compressors. Estimated cost, \$33,000. O. W. Sparks, superintendent.

**TRECE**—The Miami-Texas Mining Co. will remodel its 250-ton concentration plant here. Estimated cost, \$25,000. The company is in the market for lumber, belts, sludge and slime tables, rollers for crushers, air compressors, conveyors, ore cars, and track. F. W. Stallings, Trece, superintendent.

#### Louisiana

**NEW ORLEANS**—The Bureau of Yards & Docks, Navy Department, Washington, D. C., will build four ammunition plants here. Estimated cost, \$4,500.

#### Maryland

**BALTIMORE**—The city will enlarge the filtration plant at Lake Montebello, build an additional filtered water reservoir and also a plant for the manufacture and storage of alum. W. E. Le Clair Hall, water engr.

**CUMBERLAND**—The American Colulose Co., 52 Vanderbilt Ave., New York City, has awarded the contract for the construction of a 1-story plant for the manufacture of cellulose for war purposes to G. A. Fuller, Fuller Building, New York City. Estimated cost, \$10,000,000.

**CURTIS BAY** (Baltimore P. O.)—The Curtis Bay Copper & Iron Works will build three-story, 70 x 120 ft. steel and hollow-tilt additions to its plant here, machine shop type. W. F. Cochrane, South Baltimore, engineer.

**INDIAN HEAD**—The Bureau of Yards & Docks, Navy Department, Washington, D. C., will build a nitrate plant here. Estimated cost, \$9,000,000.

**INDIAN HEAD**—The Bureau of Yards & Docks, Navy Department, Washington, D. C., has awarded the contract for the remodeling of chemical laboratory at the Naval Station here, to Austin Co., 1626 Bulletin Building, Philadelphia, Pa. Estimated cost about, \$25,000. Noted June 30.

**INDIAN HEAD**—The Bureau of Yards & Docks, Navy Department, Washington, D. C., has awarded the contract for the construction of a chemical laboratory here, to Austin Co., 1313 H St., N. W., Washington, D. C. Estimated cost, \$25,350.

#### Michigan

**GRAND RAPIDS**—The Volvorne Brass Works, Monroe Ave., will build a 5-story addition to its plant. Osgood & Osgood, architects.

#### Missouri

**GRANBY**—The Carolyn Metal Co., Oklahoma City, Okla., will remodel and increase the capacity of its 150-ton mill to 250 tons, and is in the market for sludge and slime tables, roofing lumber, crushers, belts and air compressors. Estimated cost, \$25,000. N. Darling, superintendent.

**GRANBY**—E. L. Plank, Everitt Smith and E. R. Rashley, will build a 150-ton concentration plant at their mine here, and are in the market for sludge and slime tables, roofing engine, ore cars, crushers, lumber, mill hardware, air compressors and conveyors. Estimated cost, \$55,000. E. L. Plank, superintendent.

**JOPLIN**—The Badger Mining Co. will build a 250-ton concentration plant and is in the market for sludge and slime tables, engine, boilers, belts, crushers, lumber,

mill hardware, ore tubs, ore cars, track, rope, and roofing. Estimated cost, \$60,000. A. Foster, 401 Miners Bank Building, manager.

**JOPLIN**—The Rashgo Mining Co., will build a 150-ton concentration plant near the Sunnyside Mine, and is in the market for sludge and slime tables, crushers, air compressors, lumber, mill hardware, conveyors, belts, track and cars. Estimated cost, \$15,000. W. M. Randell, Joplin, superintendent.

**ORONOGO**—A. F. Hott will rebuild the 200-ton concentration plant at his mine, recently destroyed by fire, and is in the market for sludge and slime tables, oil engine, belts, air compressors, rollers, mill hardware, drills and ore crushers. Estimated cost, \$25,000.

**SENECA**—The Mt. Nebo Lead & Zinc Co. will build a 200-ton concentration plant, and is in the market for mill lumber, mill hardware, belts, cables, ore cans, sludge and slime tables, ore crushers, conveyors, air compressors, boilers and engine. Estimated cost, \$40,000.

**ST. LOUIS**—The Mousanto Chemical Works, 1800 South Second St., will build an addition to its plant. Brenneke & Pay, 1000 North Third St., engineers.

**ST. LOUIS**—The Moon Motor Car Co., 4401 North Main St., has awarded the contract for the construction of a 4-story, 50 x 126 ft., reinforced concrete, munition factory, to Greve Construction Co., Century Building. Estimated cost, \$48,000. Noted June 15.

**ST. LOUIS**—The Scullin Steel Co., 6700 Manchester St., has awarded the contract for the construction of a 2-story, 41 x 283 ft., reinforced concrete, brick and steel munition plant at 2514 Ecoff St., to Crowell, Lundorff, Little Co., 1951 East Fifty-ninth St., Cleveland, Ohio. Estimated cost, \$200,000.

**WACO**—The Blue Rock Mining Co. will build a 250-ton concentration plant and is in the market for slime and sludge tables, crushers, conveyors, air compressors, lumber, mill hardware, roofing, engine and boilers. Estimated cost, \$60,000.

**WACO**—The Miami-Waco Lead & Zinc Co. will build a 250-ton concentration plant requiring ore crushers, engine, compressors, rollers, and sludge and slime tables. The slime tables, belts, lumber, ore cars and track. Estimated cost, \$40,000. W. P. Cunningham, Waco, superintendent.

**WACO**—The Central Zinc Co. will remodel the 400-ton mill which it recently purchased and install mill hardware, lumber, sludge tables, air compressors, rollers, ore crushers, boilers, ore cars and track. Estimated cost, \$20,000. Frank Dangleade, Waco, superintendent.

**WACO**—The Crescent Lead & Zinc Co. will build a 250-ton concentration plant. Estimated cost, \$35,000. The company is in the market for gas shovels, rollers, air compressors, rollers, tables, jigs and mill hardware. Glen Smith, Waco, superintendent.

#### New Jersey

**BLOOMFIELD**—The International Arms & Fuse Co., Bloomfield Ave., will build a 3-story, 75 x 100 ft. addition to its plant.

**HARRISON**—The Crucible Steel Co., Sixth Fourth St., has awarded the contract for the construction of a 1-story, 70 x 100 ft. rolling mill, to W. H. & W. Cane, Woolworth Building, New York City. Estimated cost, \$500,000.

**JERSEY CITY**—The Metal & Thermit Corporation, 527 Johnston Ave. it recently built a 1-story, 35 x 100 ft. steel plant. Estimated cost, \$15,000.

**KEARNBY** (Arlington P. O.)—Henry Field, Detroit, Mich., will build a 1-story, 400 x 1100 ft., brick and steel cetry on the Passaic River here for the construction of patrol boats and submarine chasers. Estimated cost, \$2,000,000.

**NEWARK**—The Fetterworth-Judson Co., 1000 Broad St., will build a 40 x 84 x 60 ft., brick and steel chemical plant. Estimated cost, \$118,000.

**NEWARK**—The E. I. duPont de Nemours & Co., duPont Building, has awarded the contract for the construction of a 1-story, 28 x 49 ft. and 2-story, 28 x 103 ft., brick factory buildings, to G. Tomlinson & Son, 2619 South 12th St., Philadelphia, Pa. Estimated cost, \$27,150.

#### New York

**RUFFALO**—The Atlas Steel Castings Co., 1963 Elmwood Ave., has awarded the contract for the construction of a 1-story, 30 x 200 ft. plant, to the Austin Co., 16112 Euclid Ave., Cleveland, O.

**BUFFALO**—The Linde Air Products Co., 155 Chandler St., has awarded the contract for the construction of a 1-story plant on Fillmore Ave., to J. W. Cowper Co., Fidelity Building. Estimated cost, \$10,000.

**CHATEAUGAY**—The High Falls Pulp & Paper Co. will build a 1-story, reinforced concrete and brick pulp and paper mill. Estimated cost, \$75,000. Thompson & Henger, Gurney Building, Syracuse, engineers.

**HASTINGS**—The Cantonment Division, War Department, Washington, D. C., will build a large chemical plant here for the use of the Ordnance Department. First unit to cost, \$500,000.

## Olio

**CLEVELAND**—The Great Western Oil Co., 2846 East Thirty-seventh St., will build an oil refining plant to replace the one recently destroyed by fire. W. W. Hodges, Snodell Building, architect.

**CLEVELAND**—The Lakeside Hospital, Lakeside Ave. and East Twelfth St., has awarded the contract for the construction of a 2-story, 42 x 62 ft., brick and concrete addition to the laboratory, to Crowell, Lundoff, Little Co., 1951 East Fifty-seventh St. Estimated cost, \$20,000.

## Oklahoma

**CENTURY**—The Crescent Mining Co. will build a 200-ton concentration plant. Estimated cost, \$45,000. The company is in the market for sludge and slime tables, crushers, conveyors, air compressors, jigs, belts, mill hardware, mill lumber, roofing, engine and cables. H. L. Woods, Commerce, superintendent.

**COMMERCE**—The Big Jim Mining Co. will build a 200-ton concentration plant. The company is in the market for mill lumber, roofing, sludge and slime tables, mill hardware, engine, crushers, air compressors, jigs and conveyors. Estimated cost, \$60,000. G. W. Nesmith, Commerce, superintendent.

**COMMERCE**—The Miami Volunteer Mining Co., Miami, will remodel and enlarge its 200-ton concentration plant, which is in the market for sludge and slime tables, oil engine, belts, mill hardware, lumber and crushers. Estimated cost, \$25,000. J. L. Hawthorne, Tulsa, Okla., superintendent.

**DOUTHAT**—J. J. McElahan and Ray Munson will build a 500-ton concentration plant at their mine and are in the market for sludge and slime tables, jigs, cleaner, crushers, lumber, hardware, engine and rollers. Estimated cost, \$65,000. Ray Munson, Douthat, superintendent.

**HOCKERVILLE**—McCurdy Bros. Mining Co., Quapaw, will build a 200-ton concentration plant and is in the market for sludge and slime tables, mill hardware, rollers, engine, air compressors, conveyors and crushers. Estimated cost, \$65,000.

**HOCKERVILLE**—The Tulsa-Sulphur-Miami Associated Mines Co. will build a 200-ton concentration plant and is in the market for sludge and slime tables, crushers, pipes, lumber, hardware, air compressors, conveyors, roofing and engine. Estimated cost, \$65,000.

**LAWTON**—The Development Co. will remodel its concentration plant increasing the capacity from 250 tons to 500 tons and is in the market for sludge and slime tables, air compressors, rollers, pipes, rollers, crushers, mill hardware, mill lumber, and ore cars. Estimated cost, \$10,000. E. E. Jancy, Lawton, superintendent.

**LINCOLNVILLE**—The White Swan Coal Co. will build a 200-ton concentration plant at its mine here. Estimated cost, \$85,000. The company is in the market for sludge and slime tables, mill lumber and hardware, air compressors, rollers, engine, rollers, engine and rollers. J. H. Stoddard, West Plains, Mo., superintendent.

**OKMUTGEE**—The city will build a filtration plant, sewage disposal plant and new main sewer. Estimated cost, \$150,000. Burns & McDonnell, 402 Interstate Building, Kansas City, Mo., engineers.

**QUAPAW**—The Allied Lead & Zinc Co. will remodel its 250-ton concentration plant and is in the market for sludge and slime tables, mill hardware, belts and compressors. Estimated cost, \$15,000.

**QUAPAW**—The Lead Cave Mining Co. will remodel its 200-ton concentration plant and install sludge and slime tables, new belts, cables, track, rope, roofing, lumber and hardware. Estimated cost, \$60,000.

**QUAPAW**—The Six Mining Co., Miami, will build a 600-ton concentration plant and

is in the market for sludge and slime tables, roofing, mill hardware, lumber, crushers and engine. Estimated cost, \$65,000.

**QUAPAW**—The Spelter Mining Co. will build a 200-ton concentration plant east of Quapaw. The company is in the market for sludge and slime tables, crushers, lumber, roofing and hardware. Estimated cost, \$65,000.

**TAR RIVER**—The Maxine Co. will build a 400-ton concentration plant. Estimated cost, \$85,000. The company is in the market for a gas drying engine, crushers, air compressors, belts, lumber, roofing, conveyors, mill hardware, sludge and slime tables, etc. W. C. Miller, Tar River, superintendent.

## Pennsylvania

**CHESTER**—The Crown Smelting Co. will build a 1-story, 17 x 100 ft., addition to its pattern works.

**ERIE**—City plans to build intercepting sewers and sewage treatment works. Estimated cost, \$300,000. Chester & Fleming, Union Bank Building, Pittsburgh, engineers.

**JANCASTER**—The Bottonfield Tire Co., Woolworth Building, will build an addition to its plant. Estimated cost, \$10,000. H. R. Evans, 104 East Orange St., architect.

**MARCUS HOOK**—The National Aniline & Chemical Co., Inc., has awarded the contract for the construction of oxide pits, to the Austin Co., 16112 Euclid Ave., Cleveland, Ohio.

**SACKETTOWN**—The Midvale Steel Co., Widener Building, Philadelphia, will build a 1-story, 113 ft. 8 in. x 48 ft. rough machine shop, a 1-story, 74 ft. 11 in. x 36 ft. 6 in. heat treatment plant, and a 1-story, 183 x 362 ft. finish machine shop, all buildings to be of steel construction.

## Rhode Island

**BRADFORD**—The Bradford Dyeing Association will build a 1-story, 69 x 200 ft., brick and timber mill building. Estimated cost, \$20,000. Jenks & Ballou, Grosvenor Building, Providence, engineers.

## Tennessee

**KINGSFORD**—The Cantonment Division, War Department, Washington, D. C., will build a large chemical plant here for the use of the Ordnance Department. First unit to cost, \$500,000.

## Texas

**CULBERSON CO.**—Edward Hart, Bartow, and others, will build a plant for refining raw sulphur and for the manufacture of sulphuric acid.

**FT. WORTH**—The city will build a sewage disposal plant. A. Lord, waterworks commissioner.

**WACO**—The city plans to build a sewage disposal plant. Rollen J. Windrow, city engineer.

## Virginia

**HAMPTON**—The Bureau of Yards & Docks, Navy Department, Washington, D. C., will build an addition to the laboratory here. Estimated cost, \$13,000.

**KERMIT**—The Carroll Development Co., 312 McMain Building, Roanoke, Va., will build a plant here for developing silica deposits. E. A. Schubert, president.

## Washington

**SEATTLE**—The Northwest Motor Co., 618 East Pike St., will build a 90 x 250 ft. steel foundry for the production of iron and steel on industrial sites 6 and 7, King Co. Estimated cost, \$150,000.

The Quilley Furnace Specialty Company, Inc., has opened a branch office in Pittsburgh at 427 Ohio Building, to handle the sale of powdered coal equipment, and Hytemple furnace cement. The powdered coal engineering department will be in charge of Mr. V. Mayo, formerly maintenance engineer of the A. M. Byers Company plant at Girard, Ohio, and the specialties department will be taken care of by Mr. J. L. Cummings, Jr., formerly connected with the sales department of the company at New York.

The Electric Furnace Construction Co., Philadelphia, recently placed in operation a 3-ton electric furnace of the Greaves-Etchells type at the plant of the Ford Motor Co., Detroit. It is operating on nickel-chrome steel for special airplane

work, producing heats in as low as 11 hours. There are a number of electric furnaces in operation but this is the first one of the type to be placed in operation in the United States. The following furnaces will be placed in operation: Two 3-ton furnaces at the plant of the Halcomb Steel Co., Syracuse, N. Y.; one 6-ton furnace at the Navy Yard, Puget Sound, Wash., and two 6-ton furnaces at the plant of the American Radiator Co., Buffalo, N. Y.

The Electric Furnace Industries War Service Committee has been organized by manufacturers of electric furnaces for the purpose of operating electric furnaces. It is apparent that there may be a need for the same. Its object is to compile and furnish information to the Government relative to electric furnace industries in the production of steel, ferrous and non-ferrous alloys, and metals where the melting problem is concerned. The following manufacturers have become members of the new organization: Hamilton & Hansell Co., New York; John A. Crowley Company, New York; Ajax Metal Company, Philadelphia; American Metallurgical Corp., Philadelphia; Electric Furnace Construction Co., Philadelphia; Pittsburgh Furnace Company, Pittsburgh; Booth-Hall Furnace Company, Chicago, Ill.; Industrial Electric Furnace Co., Chicago, Ill.; Electric Furnace & Co., New York City; Ludlum Electric Furnace Co., Woodworth Bldg., N. Y.; T. W. Price Engineering Company, New York; Beckman & Linden Corp., San Francisco, Cal.

The Wellman-Seaver-Morgan Co., Cleveland, O., has recently ordered from the H. Koppers Co. five coke pushers for the John Hancock Co., and has ordered the installation in Fairmount, W. Va. A coke pusher is also ordered for the Wipulotte Coke Oven Corporation, New York.

The Island Petroleum Co., and the Concrete Products Co., whose plants are on Seville Island, Esfuerzo, P.R., have been notified by the Government that their properties are wanted for the United States Steel Corporation's new gun and projectile plant. They have been advised that while immediate ownership is desired by the Government, actual possession is not wanted at once and they will be given enough time to remove their plants to other locations. The Witherow Steel Co., another plant on Seville Island, has been notified by the Government not to make additional improvements to the plant. It is wanted by the Government and all manufacturing plants on it will have to seek other locations.

The Cleveland Furnace Co., Cleveland, Ohio, is refining its No. 2 furnace and making other improvements to its plant which will include the building of a ladle-cleaning house, the installation of a new pig-casting machine and enlarging the furnace hearth from 15 to 18 ft., which will increase the daily capacity of the stack from 400 to 500 tons.

The Samson-Sieve Grip Tractor Co., Sacramento, Cal., is installing a 5-ton Heroult electric furnace to make steel castings.

The Enterprise Foundry, South San Francisco, Cal., has recently installed an electric furnace of its own design.

The T. W. Price Engineering Co., Inc., has just sold a 5-ton vom Bau electric furnace with bars bottom to the Hercules Steel Casting Co., Inc., Milwaukee, Wis., which is expected to be in operation by October.

The Mesta Machine Co., Pittsburgh, Pa., has placed a contract with the Smith Gas Manufacturing Co., Dayton, Ohio, for gas producers, which will be equipped to furnish 10,000 cu. ft. of producer gas every 24 hr. of 14 to 15 Btu. per cu. ft. for use in the gas plant at Mesta, Pa., near Pittsburgh, to replace both fuel oil and natural gas. The equipment will be installed in eight units, each capable of producing about 350 cu. ft. of bituminous coal per hr. The first four units installed are expected to be completed during the coming winter, the other four will be built later.

Standardization of Catalogs.—The National Association of Purchasing Agents has adopted a page measuring 7 1/2 by 10 1/2 inches as the standard size for catalogs which will be furnished to the members of the association. The new size for catalogs has been adopted by the National Retail Hardware Association and the National Association of Brass Manufacturers. The adoption of manufacturers is urged for bringing about the standardization of catalogs.

The Dorr Company will move its New York office from 17 Battery Place to the Architects Building, 101 Park Avenue, corner of 40th Street.

### Match Your Patriotism

#### Against the National Army Men

A PROGRESSIVE and trustworthy employer of a large amount of labor in a middle western metallurgical industry states that while the average wage had increased 48 per cent over that paid immediately preceding the war, the cost of getting the same work done had risen 67 per cent owing to an actual decrease in efficiency of the higher-paid labor. This is startling enough, but far more impressive when contrasted with the spirit existing for instance in our flying schools, where as one cadet put it, "If anyone had asked me to work half as hard in civil life for double the pay I would have laughed at him."

Un-Americanism infiltrates throughout industry; pure Americanism is rampant among our flyers. Industry is packed with immigrants foregathering in unlovely settlements, stewing in ignorance and squalor, this mass being more or less feebly leavened with native unionists bred with limitation-of-output ideas and superintended too often by "slave drivers" pure and simple. On the other hand, our flyers are gathered from our colleges, universities and technical schools, those institutions at once the child and mother of liberty, and are officered by self-sacrificing patriots and scholars. One's pride in our soldiers matches illy his apologetic toleration of wage- and business-profiters.

As recent events show, we Americans need a rude jolt to waken us—a tinkling alarm cannot penetrate our complacent superficiality, our inability to pursue an idea to its ultimate conclusion. For instance, in response to early warnings of impending fuel famine, New York City darkened Broadway! Officialdom also seems to bow to the great American ego when it exempts taxi-drivers from the "Work or Fight" order. We adopted the selective draft because we knew that volunteering in mass would not follow war's declaration. We are too heterogeneous to act with unanimity: scant majorities rule. Yet we could not bring ourselves to the equally obvious draft of the production indispensable to maintain our growing army. Too many manufacturers refuse munition orders at 15 per cent profit when peace orders net many times more. Priorities may force a change of heart; lack of coal, lack of steel, lack of transportation, will doubtless temper "business patriotism."

But how can we bring workers into shipyards, munition works, food production? How impress them with the idea, as William Hard puts it, that it is just as wrong to abandon a gun-carriage which is being made to kill Germans as to abandon a gun-carriage which is killing Germans? Conscription of labor—the corollary of conscription of fighters and the conscription of industries—naturally is not popular with the workers.

even though it is virtually in effect under the provisions of the selective draft which allows industrial exemption. Yet any class should realize that a draft is surely coming unless the impossible ensues, unless they volunteer *en masse*. As far as the native worker is concerned, the impossible might be possible, if he were sure that the sacrifice of his present status would not redound to the employers' immeasurable profit.

Here a campaign of education would help; indeed where would it not help? For instance, the employers might well recognize the fact that they may tardily institute Americanization classes among the immigrants they are largely responsible for, seriously endeavor to improve working, housing and cultural surroundings of their workers, and seek by every means possible an *entente cordiale* between all parts of their organization.

Employer and employee alike must give and not grasp. Give until it hurts, even to surrendering conflicting "rights." Match patriotism and sacrifice with the sacrifice of the national army men, and you, as they, will be new born, will gain more than lose, and emerge better and cleaner citizens of America.

### Germany's Finger in the Platinum Pie

FIRST let us dig up a little history. Thirty years ago the world's headquarters for platinum were with Johnson, Matthey & Co., Ltd., of London. Then, following the path of trade in many other branches of industry, the Germans took a hand and there arose one Heraeus, who became a man of might. The American manufacturing business was promising but undeveloped, although it started here. There was the Bishop concern in Pennsylvania and Baker & Co. of Newark, both small, the latter also refining gold and silver from jewelers' sweepings, photographers' residues, etc. In the meantime an understanding appears to have been reached between Heraeus in Germany and Johnson, Matthey & Co. in England.

Next we observe the organization of the American Platinum Co. of Newark, and find Mr. Charles Engelhardt in control, seconded in time by his able assistant, Dr. Zimmermann, a reserve officer of the German army. Mr. Engelhardt also came from Germany, but whether he was sent here as an agent of Heraeus or came independently we do not know. Soon the Baker establishment began to expand, far beyond the means and credit presumably available to the firm as it was, and they proceeded to make platinum stills for sulphuric acid and other apparatus on a large scale. We do not affirm that these extensions were paid for by German capital, we merely state our understanding that a large percentage of the stock was soon owned by Heraeus and Engelhardt on the one hand and an equal share by Johnson, Matthey & Co. on the other. Heraeus also is said to have owned a one-fifth interest in Johnson, Matthey & Co.

Shortly after the enlargement of the Baker concern and the accession of new interests, the price of platinum advanced out of all proportion; far higher than trade conditions warranted. The situation displayed all the stigmata of the presence of a regular, old-fashioned, millions-in-it trust. The senior Baker died and so did one of his sons, leaving Cyrus O. and Charles in the business. Now Cyrus also is dead, and while Charles

still participates in it, the platinum headquarters in America are to be found under Mr. Charles Engelhardt's hat and not elsewhere. In the meantime Baker & Co., Inc., are reported to have gone into the manufacture of platinum jewelry mountings on a large scale.

The complexities of German ownership grew apace. There was the Croselmire concern which was originally a gold and silver refinery similar to the original Baker house, and a competitor. This was taken over by Roessler & Hasslachner who proceeded to offer platinum and platinum compounds for sale. Roessler & Hasslachner are or were connected with and established by the Deutsche Gold & Silber Scheideanstalt at Frankfurt on the Main. What the relations between the Scheideanstalt and Heraeus are we do not know, but the disposition of German houses is to be friendly in foreign trade. Neither can we give the relations between the corporations named and other refiners of the metal in this country except to note that the trade seems to be closely organized.

Whatever the original composition of the international platinum syndicate, it is evident that Johnson, Matthey & Co. dropped out when the war began and they have had to shift for themselves. We are informed that Mr. Engelhardt and his friends have taken over the Heraeus interests in the American organizations. He is, we understand, an American citizen, and he has functioned as the advisor in regard to the metal with which he is abundantly familiar, to the Division of Chemistry of the War Industries Board. The chairman of this department is Mr. L. L. Summers. And here we reach a situation that we would like very much to have explained.

Mr. F. W. Draper brought over from Russia for sale 20,000 ounces of platinum which was the property of the Russian and English Bank. He was authorized to sell it for \$105 an ounce. On the arrival of the metal in New York it was commandeered by the War Industries Board. There followed a series of interviews between Messrs. Summers and Draper, in which Mr. Summers offered to pay \$90 an ounce for it and no more and refused to let it be sold elsewhere. Mr. Draper protested and so did the Bank, claiming that this would involve the institution in serious financial loss, but \$90 an ounce is all they received. Mr. Draper said that the bank had 15,000 ounces more for sale and that at the time they were able to produce and deliver still more, but it is also said that after the \$90 episode they gave up the idea of sending any more platinum to the United States. Now if the German interests wanted to prevent the metal from reaching this country so as to make us slow down on the production of the needed *plum* for munitions they could not have asked for a more effective means to accomplish their purpose.

The present situation is that we need more platinum than there is in sight. That is a fact and we are not interested in the opinions of laymen as to what substitutes are available for various purposes or what the effect of such steps as may be necessary will be upon the 1918 profits of the jewelry trade. What we would like to know is whether Mr. Summers cut the price for Mr. Draper from \$105 to \$90 on the advice of Mr. Engelhardt or on his own initiative. If it was wholly on his own initiative it was a blunder—but we all make mistakes. On the other hand, if it was at the

suggestion or on the advice of Mr. Engelhardt, who is too well posted on platinum affairs to make serious errors in calculation, it will establish in us the fear that he is still a little too close to the Heraeus outfit to be an entirely safe advisor in time of war.

There has been too much talk and too little doing in this matter. It is amazing to consider that serious men will listen to the effort to balance up fashions and styles in jewelry with the country's need in its hour of peril. There is just one way out of this difficulty and that is for the U. S. Government to take control and possession of every plant that handles platinum and proceed to order sales according to requirements.

The Committee on Ways and Means spent the better part of three days listening to the views of jewelers, chemists and Government representatives on the platinum situation. While the committee was not enlightened on the question of how to raise revenue from platinum, it did receive considerable information which Congress as a whole might read to its profit. By far the best advice the committee received was that there should be no platinum to tax; that the Government should gather into its vaults all platinum not now serving a useful purpose in war work and hold it against the time when it may be needed.

### **Increasing Production of By-Product Coke**

UNDER pressure of war demand for explosives, first by the Allies and then by the United States Government, there is no end to the building of by-product coke ovens. An astonishing showing is being made for these days of high construction costs. The more important items of by-product oven completion are 140 ovens put in operation at Gary early in the year; 180 ovens at Cleveland (American Steel & Wire Company), which made their first coke in May and are now in full operation; 128 ovens at Clairton (Carnegie Steel Company), which made their first coke late in June and are now in full operation, with four similar batteries of 128 ovens each to be completed at various times to December 31; 208 ovens at Lorain, O. (National Tube Company), half of which are now in operation, with the other half to be completed in 30 to 60 days; and 102 ovens at Youngston (Youngston Sheet & Tube Company), half completed and half to be completed in 30 to 60 days. Smaller completions are 65 ovens of the Minnesota By-Products Company, 24 of the Chattanooga Coke & Gas Company and 60 of the Bethlehem Steel Company at Steelton, Pa. The ovens completed this year to date represent about 3,000,000 net tons a year in actual coke production and the ovens still to be completed this year approximately as much, perhaps somewhat more, possibly somewhat less. In addition there are many projects that have been on the way for some time, together with a fresh batch inaugurated within the past three months, in some of which Government financing is involved, the builders to take the ovens from the Government after the war at an appraised valuation.

For an industry growing so rapidly the annual production reports of the Geological Survey are only of general value, for the reported production of a year does not indicate the capacity at either the beginning or end of the year or even the average capacity for

the year. The weekly reports which were instituted at the beginning of this year prove quite illuminating. They show that while the rating of a plant's capacity is done with more or less skill and definite knowledge, it varies from time to time. The reports show for each week both the rated capacity and the actual production. At a number of plants the ratings have varied according to the kind of coal they were using. During the railroad blockade of last winter some were forced to take coal that was not their choice, and their ratings were below normal for the plant. The rated capacity at the beginning of the year, given the choice of coal, was about 500,000 net tons a week. When operations became what may be considered substantially "normal," production turned out to be rather regularly about 90 per cent of rated capacity, there being an average sprinkling of plant repairs, little interruptions in coal supplies, labor difficulties, etc., that accounted for 10 per cent.

The first week in July a landmark was passed, the output for the first time being a half million tons; 502,666 tons, to be exact, with a rated capacity for the same week of 556,592 tons. There had been such an increase in the half year that the expected production, under normal conditions, would be increased by very nearly 50,000 tons, or fully 10 per cent in the course of six months. Starting the year with a rated capacity of 500,000 tons a week the industry promises to end it with about 615,000 tons capacity, from which it may be said that the expected production, at 90 per cent of rated capacity, promises to increase from 450,000 tons a week to fully 550,000 tons a week; and 1919 will show its own further increases. The rate of production at the close of 1918 should be nearly 30,000,000 net tons a year, against 22,600,900 tons actually produced in 1917. Assuming the actual production in 1918 to be 26,000,000 tons, which seems a fair guess, it may be said that in 1914, four years earlier, the output was not one-half as great; in 1909, nine years earlier, it was not one-quarter as great; in 1904, 14 years earlier, it was not one-eighth as great.

Of course there remains a great loss in volatile elements by the fact that the beehive process is still the predominating one. The weekly output of beehive coke, unlike that of by-product coke, varies so widely that a precise statement cannot be made of the average rate of production, but the average of the latest six weeks for which there are statistics at this writing shows a weekly average of 620,000 tons. To what extent the increase in by-product coke production will decrease the beehive production remains to be seen. Conditions are somewhat confusing and it is impossible to determine just how much coke the blast furnaces and other consumers will require. Much of the coal, moreover, that is used in by-product coking is drawn from beehive coking regions, and if the supply of coal controls, the beehive ovens will be closed when by-product ovens are completed, even though the preference would be to operate both. The balance of probability seems to be that if the by-product industry reaches a rate of actual production of 600,000 tons a week by the end of the year, the production of beehive coke will have dropped to less than 600,000 tons, so that then by-product coking will at last predominate. At August 1 the proportions seemed to stand about 55 to 45.

## Readers' Views and Comments

### Molecular Physics of Ore Flotation

To the Editor of *Chemical & Metallurgical Engineering*

SIR:—I note the communication from G. W. Van Arsdale in your issue of July 15, in which he offers a correction to a statement made by Mr. Anderson and myself in your issue for June 1, 1918.

In the absence of Mr. Anderson who is now in the training camp with the army engineers, I shall undertake a brief reply.

When I read the part of Mr. Van Arsdale's paper to which he refers, my mind reverted to ancient literature—ancient in terms of the age of American literature on flotation. If the reader will refer to the *Mining & Scientific Press*, vol. 3, p. 544 (1915), he will see that I once fell a victim to this same incorrect definition of surface-tension to which Mr. Van Arsdale refers. I soon discovered my mistake and hastened to correct my error, and the correction appears in vol. 112, p. 315. It was indeed a great surprise to me to find one of our leading contributors to the literature on flotation giving credence to this erroneous definition by saying: "As a matter of fact it can easily be shown that a square centimeter of water will support much more than this weight." I understand from this that Mr. Van Arsdale proposes to apply a factor, and further, that he declares that the factor shall be greater than unity. I see no element of scientific fact in this statement, because if, for example, the angle of contact is zero, the degree (factor) of flotability is also zero. For the explanation of this fact I can only refer to the article containing the paragraph with which Mr. Van Arsdale differs.

I regret it if Mr. Anderson and I have said anything that puts Mr. Van Arsdale before the readers as the chief, or only, transgressor of facts. I wish to take this opportunity to state that if a list were to be made of those who have mis-stated principles of flotation, my name should be included. In short, I believe that the only one who has not made mis-statements is the parasite who has stated nothing. There is no place in the study of flotation for the man who does not make mistakes. I once found justification in the literature on colloid chemistry for adhering to a theory, to wit, that all floatable bodies were surrounded by a liquid surface-tension film when submerged. Our study of flotability, a part of the results of which are contained in our article to which Mr. Van Arsdale refers, has convinced me that this theory is untenable.

### Flotation Apparatus

To the Editor of *Chemical and Metallurgical Engineering*

SIR:—An error has apparently crept into the minds of various writers to the technical magazines to the effect that the Towne-Flinn flotation patents concern only the cylindrical type of machine used at several demonstrations, and out of which have appeared at various times in the magazines. Also a parallel error arose to the effect that we used only a carborundum

stone as a porous medium, when, in fact, a canvas bottom was among the first used in any of the various types of machines we designed. It would seem only fair to the late Mr. Robt. S. Towne and myself to state the truth at this time.

We were led into the pneumatic process from our observations while trying to develop an acid-proof filter in 1908. At that time, in cleaning our filter medium, which chanced to be carborundum stone, we reversed the air and blew through the stone. While doing this both with canvas and porous stones, we noticed the beautiful bubble screen and the action of the sulphide present with the bubbles formed. At about that time we were also carrying on investigations with the Elmore and Murex processes, and so were quite familiar with oil processes then suggested for use. In our experiments we used the wood distillation products so commonly demanded now in flotation work. However, it was not until a later date that we developed the "bubble column process" or the pneumatic process as now carried on. Among our earliest types of machines were the cylindrical, step, cone and what we called the Type B or flowing-type machine. This last machine was remarkably similar even in small details to the so-called Callow type which was developed by Mr. Callow at a later date. In the early days certain large mining groups in our country became very much interested in our pneumatic process and a mutual understanding arose that we would demonstrate it at one of their plants in counter-distinction to the beating or froth process which was just coming into prominence, and it was with this idea of demonstrating a process and not any special type of machine that Mr. Towne agreed to their request. His idea was to avoid any competitive tests between one machine and any other, but to give a demonstration of the pneumatic process as against the Minerals Separation process. Unfortunately delays crept in from sickness and other reasons, and the greater part of a year passed before we could carry out these plans. Litigation arose; moreover, at this time the Callow machine made its debut at the National Copper Company's mill.

We were convinced that the bubble column process had advantages over the froth process and were granted our claims for a process patent by the Patent Office. Being assured of this and being advised by our lawyers that we were fully protected, we did not push the patents for the various machines as actively as we should have done. This, of course, brought about interferences in the Patent Office with Callow, Cole and others. Mr. Towne's death in 1916 stopped our active work.

While the testimony was being taken in the interference case between Callow and ourselves in 1917, a very satisfactory agreement was arrived at, and we sold our basic patent and machine applications to strong interests. This seemed a wise policy, as otherwise years of litigation might have arisen and further disturbed the mining world. If we had followed out

our first impulse we would have given the public the entire knowledge and result of our experiments in the fall of 1912, and in fact had started to write an article for publication, but came to the conclusion that it would be wiser not to do so. We did and do yet maintain that our basic patent claims will prevent the use of any pneumatic machine without our permission, but of course that can only be decided by the courts.

In making these statements, I do not want to detract from Mr. Callow's glory in pushing his ideas and advancing the art as he has. Because of Mr. Towne's death and the selling out of our patent applications, I withdrew from any active part in the flotation field with regret, as it certainly contains much of interest worthy of scientific investigation.

Our use of the carborundum stone came about from the fact that we felt sure that some way would be found to clean the air blown through the stone, for our observations led us to believe that the blanking of the air passages came from deposits on the lower sides and not on the upper surfaces. Again if the bubbles be examined in a glass tubing it becomes apparent that more bubbles were formed by passing the air through stone than through a canvas bottom. As the efficiency of the process depended on bubbles, it seemed to us at that time that the thing to do was to use the one which formed the most. But by no means were we tied down in our patents to the use of any one kind of porous medium, and felt that the best type of machine and bottom could best be decided on after a long run in the mill. As to the capacity of any machine, it seems to vary with the ore and class of material treated. I must say frankly that I am not one of those who think that the pneumatic process is the only process, for I think that there are ores where the froth process seems to give the best results, and in other cases the pneumatic.

In closing, I will say that we tried passing  $H_2S$  and  $CO_2$  gases as well as air through the bottom.

## Recovery of Molybdc Acid for Steel Mills

*To the Editor of Chemical & Metallurgical Engineering*

SIR:—The following method for the recovery of molybdc acid from the analytical filtrates of phosphorus determinations has proved very economical as well as highly desirable in maintaining a supply of that reagent.

The method consists of the precipitation of the molybdc acid from the ferric nitrate solution with an excess of phosphate. Five times the theoretical amount of phosphate is added to the boiling solution. The filtrates from 3500 cc. of ammonium molybdc solution are heated to boiling and a solution containing 200 grams of commercial sodium phosphate added. The precipitate is allowed to settle and after the solution is decanted is transferred to a large mouthed bottle. When sufficient yellow precipitate from several precipitations is obtained, it is washed by decantation, transferred to a dish, the water evaporated off and the precipitate dried on a sand bath. According to the commonly accepted formula for the yellow precipitate, it contains 92%  $MoO_3$ ; 210 grams would contain the

same weight of acid as  $\frac{1}{2}$  lb. of 85% molybdc acid. Accordingly for the precipitation of the molybdc acid solution, 210 grams of yellow precipitate are weighed and 800 cc. of water added, followed by 600 cc. of ammonia. The solution is cooled and 35 grams of magnesium nitrate, dissolved in 100 cc. of water are added to precipitate all the phosphorus. After the solution has stood for some time, it is filtered and the precipitate is washed with 100 cc. of water or dilute ammonia. The filtrate is added to 1900 cc. of 1:1 nitric acid, the total volume being 3500 cc. and containing the usual amount of ammonia and nitric acid. W. H. LYNAS.

Columbus, Ohio.

## Research Preparedness in the Zinc Industry

*To the Editor of Chemical & Metallurgical Engineering*

SIR:—I have read the interesting article by Parker C. Choate, under the above heading, in the July issue of your journal. I agree with the majority of his deductions and proposals, while some seem somewhat obscure and require further elucidation, even to one familiar with both the technical and practical side of zinc metallurgy. This is perhaps logical, in view of the radical changes proposed. I would like to know, for instance, how he proposes to extract the lead, silver and other valuable metals from the raw sulphide by leach electrolysis; also further particulars on his "volatile concentration" scheme, etc.

I do not agree with the statement that he sees little value in making sulphuric acid. On the contrary, saving the sulphur by making sulphuric acid enables the modern smelter works to survive hard times and close smelting margins, which will compel many of the antiquated plants to close down sooner or later. When it is considered that for every 100 tons of 60 per cent blende roasted in those plants, approximately 30 tons of sulphur is discharged into the atmosphere and lost, the waste becomes appalling, especially at the present time when every ton of sulphur is needed for the successful prosecution of the war. In pre-war times the sulphur value was rated at about \$1.50 per ton of ore, and at present it is safe to say that it is worth not less than \$5. Indeed, figuring brimstone containing over 99 per cent sulphur at an average value of \$30 per ton, a zinc concentrate containing 30 per cent sulphur ought to be worth \$7.50. Of course, I note Mr. Choate's plan to recover the sulphur from the calcium sulphide formed during distillation, so it would not necessarily be lost.

The writer has had no experience with briquetting the charge, but from a theoretical point of view, it seems a very promising line of investigation.

Mr. Choate's statement that pulverized coal will be found a most efficient auxiliary, is very much to the point. Years ago, while the writer was connected with a zinc smelting concern, he was first to suggest powdered coal for zinc smelting, before its recent general appreciation. The idea was taken up by the management, but the writer was given no opportunity to assist in its development during the later stages, as certain members of the management wanted to take all the credit for their own aggrandizement. This is the sad story of research in some companies at least, with non-technical superiors.

ERIC JOHN ERICSON.

Chicago, Ill.

## Solder Without Tin

To the Editor of Chemical & Metallurgical Engineering  
 SIR:—The following notes on solder may be of interest in view of the scarcity of tin and the necessity of substituting for it wherever possible. The notes are taken from the records of experiments on a somewhat different subject and are consequently incomplete.

### LEAD-CADMIUM

The lead-cadmium alloys possess some desirable properties as solders and furnish the base for addition of other metals, giving solders of different characteristics. The melting points of the lead-cadmium alloys are shown in the diagram, Fig. 1. The final hardening temperature of these is above the melting point of ordinary solder. However, this would constitute an advantage for many purposes.

The following tests show the relative strengths of joints soldered with lead-cadmium alloys and pure tin at various temperatures. The tests were made by pulling apart two copper rods ( $\frac{1}{8}$ -in. diam.) which had been soldered end to end. The strengths of the joints are expressed in pounds necessary to pull apart a union of 1 sq.in. surface. The tests at elevated temperatures were made by immersing the soldered pieces in an oil bath. The 8 to 9 per cent Cd solder seems to be the best, cost as well as strength being considered.

### RELATIVE TENSILE STRENGTHS OF JOINTS SOLDERED WITH LEAD-CADMIUM ALLOYS AND PURE TIN

| Per Cent Cd   | Melting Range, Deg. C. | 20° C. | 110° C. | 150° C. | 290° C.               | 245° C. |
|---------------|------------------------|--------|---------|---------|-----------------------|---------|
| 2             | 290-320                | 8,920  |         |         |                       |         |
| 2.5           | 270-300                | 9,700  |         |         |                       |         |
| 4             | 249-295                | 13,000 |         |         |                       |         |
| 6             | 249-285                | 13,250 |         |         |                       |         |
| 7             | 249-280                | 12,730 |         |         |                       |         |
| 8             | 249-278                | 16,650 | 10,350  | 5,630   | 3,570                 | 2,080   |
| 8.5           | 249-275                | 17,300 |         |         |                       |         |
| 9             | 249-274                | 16,800 |         |         |                       |         |
| 10            | 249-273                | 14,000 | 6,120   | 5,540   | 3,030                 |         |
| 20            | 249-259                | 12,350 |         |         |                       |         |
| 30            | 249-260                | 16,800 |         |         |                       |         |
| 50            | 249-273                | 12,380 |         |         |                       |         |
| 75            | 249-280                | 11,200 |         |         |                       |         |
| Pure tin      | 232                    | 14,100 | 6,450   | 5,350   | 3,770 (1,530 at 230°) |         |
| Pure lead     | 327                    | 7,130  |         |         |                       |         |
| Pure cadmium  | 321                    | 6,620  |         |         |                       |         |
| Half and half | 180                    | 14,800 |         |         |                       |         |

There are several difficulties which are encountered in the use of these solders. They cannot be used with the usual soldering fluxes, although glycerine gives fair results. The best flux which we were able to find is the following mixture of fused chlorides:

|                    | Per Cent |
|--------------------|----------|
| Sodium chloride    | 11       |
| Potassium chloride | 14       |
| Zinc chloride      | 65       |
| Ammonium chloride  | 10       |

This may be used sparingly either melted or in dilute aqueous solution. This flux cannot be used in soldering complicated parts, such as electric motors, where it is impossible to remove all traces of excess flux. Metallic salts cause corrosion of copper on prolonged exposure to the air. With zinc chloride the corrosion takes place in a very short time.

Furthermore, the solder does not flow well on cold copper. It is necessary to heat the copper rather hot, and this often results in oxidation. The cadmium begins to oxidize about 30 deg. above the melting point of the solder. Consequently, it is necessary to maintain a very even temperature if the solder is to be used in a soldering pot. Under ordinary shop conditions, such use would not be practical.

### LEAD-CADMIUM-TIN

Several references have been made recently to solder composed of lead, cadmium and tin. Our experiments with this solder were somewhat limited, but it was our experience that the addition of tin lowered the melting point of the solder as well as the strength of the soldered joint. The solder did not seem easier to flux than the lead-cadmium solders unless a large amount of tin

FIG. 1.—MELTING POINTS OF LEAD-CADMIUM ALLOYS

were added. Metallic chloride fluxes seemed to be required in most cases where these solders were tried.

### LEAD-CADMIUM-ZINC

Lead-cadmium alloys do not seem to dissolve zinc in quantities much above 1.5 to 2 per cent. Upon slow cooling excess zinc rises to the top bearing with it lead and cadmium. By stirring well before pouring, solders have been made with excess of zinc over that required for solution and the solders appeared to give good results. Tests of strength of soldered joints between copper rods showed values equal to those obtained by tin, half and half, or lead-cadmium solders at room temperatures. No tests were run at elevated temperatures. The fused chloride flux above mentioned may be used with these solders; but very good results were obtained by using a mixture of rosin, ammonium chloride and alcohol. The best solders appear to be those with a relatively small amount of zinc, especially where the soldered joint cools slowly or where the layer of solder is thick. A slight excess of zinc did not appear to lower the strength of the solder, those composed of 5 per cent zinc added to the 8.5 per cent Cd-92.5 per cent Pb above mentioned, giving excellent tests. Such a solder may be used with an iron where the work is not heavy. It solders well on tin, zinc, copper and iron. Clean tin sheet can be soldered without the use of a flux. The melting range is about 250-280 deg. C., depending upon composition.

There seemed to be but little trouble from oxidation even when the solder was overheated. Such solders would seem, on the basis of our limited experience, to be applicable to a wide variety of work.

Many of the data given above were obtained by Mr. Geo. P. Luckey, who has since entered the service.

CHARLES W. HILL.

 East Pittsburgh, Pa.

## War Industries Board Discourages Further Expansion of Electric Steel

**M**ANUFACTURERS of electric furnaces in the United States have recently been confronted with the possibility of curtailing their business on account of the reported attitude of the War Industries Board against further expansion in the electric steel industry. When the matter was brought to the attention of CHEMICAL AND METALLURGICAL ENGINEERING we took the matter up through our Washington office and were informed that the Board was granting no new permits for electric steel plants in the restricted power districts of New England, and that the controlling factor was an ample supply of electric steel. On inquiry among electric furnace manufacturers we discovered that various reasons had been assigned to them, among others being the shortage of electrodes, shortage of power and a supply of electric steel in excess of demand. It was also ascertained that individual furnace manufacturers were acting on their own initiative in protest against the action of the Board, feeling that too drastic action might be taken that would vitally effect the furnace business. We have since suggested to all makers of electric furnaces in the country that they unite in the presentation of their side of the case to the War Industries Board, so that nothing will be done without thorough understanding of conditions, both by the Board and the manufacturers.

In the meantime the case for electric steel and the electric furnace has been brought to the attention of the Board through communications which we reproduce herewith in part.

Mr. C. H. BOOTH, of the Booth-Hall Co. has addressed the Board as follows:

We wish to vigorously protest against this action on your part. As a member of the American Iron and Steel Institute, the writer was present at the spring meeting in New York City, and heard Mr. J. L. Replogle make a public statement that the steel demands for building of ships and the requirements of the Army and Navy were so great that it was very doubtful whether the entire steel production of the United States would be adequate to take care of the demand as fast as would be required. We cannot understand why conditions should have changed within the last sixty days to such an extent that you are warranted in discouraging the building of new steel capacity. The more electric furnaces that are placed in operation producing steel either in the form of high-grade alloy and tool-steels or high-grade steel castings, the more will the open-hearth and bessemer capacity be available for the manufacture of plates, structural steel and the other more common grades which are so much needed. In the steel casting field there will be released similar capacity for the manufacture of heavy castings where weight is the chief essential, or for the manufacture of ingots to be rolled into finished steel.

### GOVERNMENT SHOULD AID ELECTRODE MANUFACTURE

Mr. DuBois has suggested that there is liable to be a shortage of electrodes, and for that reason the installation of new electric furnace capacity should be held back. On the other hand, we wish to point out that if the use of electric furnaces is encouraged, and not discouraged, it will stimulate the electrode industry. Why not aid the present manufacturers of electrodes to increase their capacity, or encourage the formation of new companies? With government aid, many problems much more complicated and technical than the manufacture of electrodes have been mastered and large outputs obtained. The manufacture of electrodes is quite simple by contrast and should be quickly and easily handled.

The merits of the electric furnace in conservation of materials were set forth by Mr. BOOTH as follows:

*Conserving Manganese.* The atmosphere in an electric furnace is either neutral or reducing. In either case there is no air draft to burn out the manganese contained in the steel or to oxidize the steel. Consequently less manganese need be added to make up losses and to deoxidize the steel. As contrasted with the electric furnace, the open hearth requires 50 to 100 per cent more and the steel converter 100 to 200 per cent more manganese. The electric furnace requires approximately 10 pounds of ferromanganese per ton of mild steel, so that the saving will be from 5 to 10 tons of ferromanganese to each 1000 tons of steel.

It is the usual practice in steel plants to add ferromanganese and spiegeleisen to steel, either in cold or pre-heated form. By melting the manganese in an electric furnace and adding it to the steel in molten form, the quantity of manganese needed to deoxidize the steel is greatly reduced. An article in the December 15, 1917, issue of METALLURGICAL AND CHEMICAL ENGINEERING, on pages 702-704, gives figures showing an actual saving of 44.3 per cent by adding molten ferromanganese as against adding pre-heated ferromanganese. The figures in question showed a consumption of 22.5 pounds of pre-heated ferromanganese per long ton of steel against 9.9 pounds of molten ferromanganese. This represents a saving of more than 560 long tons of ferromanganese per 100,000 tons of steel. Compared with adding ferromanganese cold the saving will be even larger.

The general use of the electric furnace for melting manganese additions to bessemer and open-hearth steel would result in reducing the requirements for manganese by nearly half.

*Conserving Pig Iron.* Both the open-hearth and converter processes when used for melting cold stock demand the use of pig iron and steel scrap. The proportion of pig iron to steel scrap depends upon the individual plant practice, but it may be said that approximately 40 to 60 per cent pig iron is used in converter practice and 25 to 40 per cent pig iron in open-hearth practice. The electric furnace processes alone allow the use of 100 per cent steel scrap without any pig iron being needed. The use of the electric furnace in place of the open-hearth and converter for melting cold stock wherever practical would result in a conservation of pig iron, releasing a large tonnage of pig iron for other purposes.

*Conserving Plumbago.* Plumbago is used extensively in the manufacture of crucibles. Crucibles are used extensively for the melting of brass and the production of tool-steels. The electric furnace is being used widely for the production of tool-steels, and there are still many plants using the crucible process which could change over to the electric process with profit. The use of the electric furnace for brass melting is still in its infancy and offers possibilities that may one day rival the use of the electric steel process. The use of the electric furnace in place of crucibles for brass and tool-steels would result in releasing a large quantity of plumbago for other necessary purposes.

*Conserving Coke.* The converter process of melting cold stock requires the use of a ton of coke to every 3 or 4 tons of steel. The electric process requires the use of no coke whatever. The use of the electric furnace in place of the converter for melting cold stock would release many thousands of tons of coke for other purposes yearly.

*Conserving Steel and Iron.* In every melting process there are losses of materials. Melting cold stock the loss will be from 7 to 11 per cent in large open-hearths, from 10 to as high as 25 per cent in small open-hearths and from 18 to 25 per cent in steel converters. In the electric furnace, the melting loss has been demonstrated to be approximately 4 per cent, this low figure being due to the absence of any oxidizing draft in the electric process. The use of the electric furnace in place of open-hearth or converter for melting cold stock would result in a saving of from 3 to 21 tons of steel for every 100 tons produced. This represents a conservation of natural resources.

The essentials to the operation of electric furnaces are electric power and electrodes. Of electric power, both steam and water generated, there is excess available throughout the country, particularly in the South, Middle West, Northwest, and West. Of electrodes there tends to be a shortage due to the expansion of

electrode manufacture not keeping step with the rapid expansion of the electric furnace industry. This is the only condition that must be taken care of in order to permit of installing additional electric furnaces and effecting the conservation of necessary materials as listed above. It is a condition easily remedied as the production of electrodes requires comparatively small investment and is a fairly simple process that has been thoroughly worked out in existing plants.

It is our contention:

First:—That the Government through the War Industries Board should encourage and aid the expansion of the electrode making industry, using methods similar to those used in increasing the output of other necessary materials.

Second:—That the Government should not restrict the installation of electric furnaces to the limited supply of electrodes, but should encourage the production of electrodes on a scale to keep pace with the growth of the electric furnace industry.

Third:—That the Government should encourage in every way the replacement of converters by electric furnaces for melting cold stock so that the considerable saving in pig iron, coke, manganese, and steel may be secured.

Fourth:—That the Government should encourage wherever practical the installation of electric furnaces for the melting of manganese additions to Bessemer and open-hearth metal.

Fifth:—That the Government should encourage the replacement of small open-hearth furnaces for melting cold stock and of crucible furnaces for brass and tool steel by electric furnaces.

Mr. VOMBAUR, of the T. W. Price Engineering Co., approached the matter from a different angle, and showed the advantages of the electric furnace in reducing the expense of transportation of materials and the release of rolling stock for other purposes.

We have a case in mind where 5300 hydro-electric horsepower is available on the Pacific Coast, where a large forge shop is now purchasing open-hearth ingots from the East. These are usually made from direct-metal refined in the open-hearth. The great saving in freight by making electric steel on the Pacific Coast rather than buying ingots in the East is indicated in the appended table, calculated on a 1000-ton basis.

|                                                                                               | Tons      |
|-----------------------------------------------------------------------------------------------|-----------|
| Iron ore, 50% Fe .....                                                                        | 2,000     |
| 20% crop of open-hearth ingots.....                                                           | 200       |
| Coke, 114% x 2200 tons (Forsythe).....                                                        | 2,508     |
| Coal, at least 133% of coke.....                                                              | 3,344     |
| Limestone, 112% x 2200 tons (Forsythe).....                                                   | 2,464     |
|                                                                                               | 10,516    |
| Ingots themselves .....                                                                       | 1,000     |
|                                                                                               | 11,516    |
| Less scrap hauled for electric furnace plant from Pacific Coast ports, plus 10% for crop..... | 1,100     |
| Saving in tonnage .....                                                                       | 10,416    |
| Mileage for railway haul.....                                                                 | 400       |
| Ton-miles .....                                                                               | 4,166,400 |
| Cost at one cent per ton-mile.....                                                            | \$41,664  |

This case is typical of many others, and since the electric furnace in making steel of whatever nature usually uses over 95 per cent scrap, and in some cases all scrap, it is evident that it is one of the greatest economic factors in the iron and steel industry to-day. The situation represented in the tabulation does not consider the fact that from 17 to 19 pounds of either 70 or 80 per cent ferromanganese or an equal amount of ferrosilicon is required by the open-hearth furnace per ton of steel, while the electric furnace requires but half as much. Also the supplies required to keep an electric furnace going are much less than those required to continue an open-hearth or Bessemer in operation. Again, the higher ignition loss in the open-hearth furnace as compared with the electric furnace does not appear in the computation.

## Government Needs Thousands of Draftsmen for War Work

THE vast activities of the Government in construction and manufacture in connection with the war program necessitate the employment of literally thousands of additional draftsmen of various kinds. The United States Civil Service Commission, whose duty it is to recruit these civilian positions, announces vacancies in large numbers of drafting positions. The filling of these positions is urgently necessary, as they have a direct connection with the war organization. Applicants will not be required to report at any place for examination, the ratings being based upon the applicant's education, training, experience, etc., as shown by the application and corroborative evidence. Full information and application blanks may be obtained by communicating with the United States Civil Service Commission, Washington, D. C., or with the secretary of the board of civil service examiners at Boston, New York, Philadelphia, Atlanta, Cincinnati, Chicago, St. Paul, St. Louis, New Orleans, Seattle, or San Francisco.

Following is a list of the drafting positions now open in the civil service, and the entrance salaries paid:

### WAR DEPARTMENT

#### Construction Division

| Title                                  | Sex | Usual Entrance Salary |
|----------------------------------------|-----|-----------------------|
| Architect .....                        | M   | \$2500-\$3500 a year  |
| Structural designer .....              | M   | 2400-2700 "           |
| Architectural designer .....           | M   | 2100-2700 "           |
| Senior architectural draftsman .....   | M   | 1800-2100 "           |
| Junior architectural draftsman .....   | M   | 1200-1800 "           |
| Architectural tracer .....             | M   | 1000-1200 "           |
| Quartermaster Corps and Ordnance Dept. |     |                       |
| Automotive engineer .....              | M   | 2400-7200 "           |
| Automotive engineer .....              | M   | 1800-3000 "           |
| Automotive draftsman .....             | M   | 1400-2000 "           |
| Automotive tracer .....                | M   | 1000-1400 "           |

#### Signal Service

|                                         |     |             |
|-----------------------------------------|-----|-------------|
| Aeronautical mechanical draftsman ..... | M   | 1200-1400 " |
| Ordnance Dept.                          |     |             |
| Mechanical draftsman .....              | M&F | 800-1800 "  |
| Gauge designer .....                    | M   | 2000-3000 " |
| Automobile draftsman .....              | M   | 800-1800 "  |
| Apprentice draftsman .....              | M   | 480 "       |

### NAVY DEPARTMENT

|                                                                               |     |                     |
|-------------------------------------------------------------------------------|-----|---------------------|
| Ship draftsman .....                                                          | M&F | \$4.00-\$6.88 a day |
| Architectural, mechanical and structural-steel draftsman (for ship work)..... | M&F | 4.00-6.88 "         |
| Topographic and subsurface draftsman .....                                    | M   | 1.48-5.04 "         |
| Radio draftsman .....                                                         | M&F | 3.52-6.00 "         |
| Copyist draftsman .....                                                       | M&F | 2.00-3.44 "         |
| Bureau of Yards and Docks                                                     |     |                     |
| Mechanical draftsman, armor and steel plant.....                              | M   | 4.00-8.00 "         |
| Engineering draftsman .....                                                   | M&F | 3.04-7.04 "         |
| Bureau of Ordnance                                                            |     |                     |
| Mechanical draftsman .....                                                    | M&F | 4.00-7.84 "         |
| Bureau of Construction and Repair                                             |     |                     |
| Metal furniture draftsman.....                                                | M   | 4.00-6.00 "         |
| Aeronautic draftsman .....                                                    | M   | 4.00-5.04 "         |
| Bureau of Steam Engineering                                                   |     |                     |
| Electrical draftsman .....                                                    | M&F | 4.00-6.40 "         |
| Marine engine and boiler draftsman .....                                      | M&F | 3.28-7.04 "         |

### INTERIOR DEPARTMENT

#### Geological Survey

|                                     |     |                      |
|-------------------------------------|-----|----------------------|
| Copyist topographic draftsman ..... | M&F | \$1100-\$2000 a year |
|-------------------------------------|-----|----------------------|

### DEPARTMENT OF COMMERCE

|                                              |   |                    |
|----------------------------------------------|---|--------------------|
| Hydrographic and topographic draftsman ..... | M | \$1000-1200 a year |
| Apprentice draftsman .....                   | M | \$60 a month       |

## Chemical Exposition to Demonstrate American Independence

THE Fourth National Exposition of Chemical Industries, to be held in Grand Central Palace, New York, September 23 to 28, will demonstrate through the multitude of new products exhibited that the American chemist has answered fully the call made upon him since the present war began. It will prove conclusively that the chemists had the ability and the knowledge to develop the facilities for making practically all of the products heretofore believed impossible to be made here. Like our fighting forces they have accomplished in a few years what it required Germany nearly fifty years to do.

The exhibits will cover a wide range from the raw materials of the ground to the highest processes for refining and producing the finished product. The exposition will cover all the ramifications of the chemical and allied industries and men in every branch of industry will find therein the materials and machinery that they can apply in their operations. It will be an exposition for the utmost in efficiency, progress and inspiration.

Coincident with the exposition will be held a number of important conferences which will bring thousands of chemists to New York from all parts of the country. The theoretical and practical phases of chemistry will be not only discussed thoroughly but illustrated as well. Men prominent in various branches of industry, bankers and government officials will be on the daily programs along with the leaders in the chemical world. The exposition will bring together manufacturers of machinery, equipment, supplies etc., and with them will come men who will explain their operation. Many intricate machines built since the United States entered the war will be exhibited and these will prove interesting and instructive. Generally speaking, the exposition will be a big school of learning and any one who misses it will have cause for regret. The papers to be read will give some idea of the remarkable things being done by American chemists in the war and industry and these will also be of interest to the general public. Pressing chemical problems concerning many of the chief articles of domestic and foreign commerce will be taken up during the conferences and it is expected that these discussions will have an important bearing on the manufacture of articles that have been scarce and high-priced ever since the curtailment of American commerce with Germany and other countries.

The exposition is a war-time necessity, and regarding it as such each exhibitor is planning his exhibit so that it will be of greatest benefit to the country through the men who visit it, all of whom are bent upon a serious purpose—that of producing war materials in large quantities, and constantly increasing this production till the war has been won by the United States and her allies.

Manufacturers, large and small, are showing unusual interest in the exposition and applications for space have been so numerous that Charles F. Roth and F. W. Payne, the managers, have made special provisions for housing the displays. The various floors which will be utilized to display the products of the industry will be filled to overflowing with everything that is new and interesting in the chemical field.

The program for the exposition is now being prepared. There will be a series of symposia on the "Development of Chemical Industries in the United States, notably since July, 1914." This will embrace the period since the beginning of the European war, which by removing the source of supply for our domestic industries, inspired the development of our own chemical industries that are so efficient in the war. There will be pictures of many chemical, mining and related industries. In fact every field of endeavor from the products within, upon and above the earth with which chemistry deals, will be shown. There will be a series of films depicting carelessness, the destruction of life, wealth and resources, that show hazards and risks in industrial plants and how they may be overcome. The dangers of fire and explosives will be demonstrated and the prevention of disease by vaccines illustrated.

The complete program of speakers and motion picture program will be announced in our Sept. 1 issue.

Some sections of the South again are sending exhibits. Canada is taking the opportunity of presenting the materials it has available for development by the chemist and financier. Technical and business men all over the country should give heed to these exhibits since they will show how they can meet the war time need. A section for the glass and ceramic industry has been added with which the American Ceramic Society is co-operating.

The advisory committee is composed of Charles H. Herty, chairman, Raymond F. Bacon, L. H. Baekeland, Ellwood Hendrick, Henry B. Faber, Bernard C. Hesse, A. D. Little, Wm. H. Nichols, R. P. Perry, H. C. Parmelee, G. W. Thompson, F. J. Tone, T. B. Wagner and M. C. Whitaker. Charles F. Roth and F. W. Payne are the managers.

## The Sulphur Monopoly and Sulphuric Acid in Georgia

The Geologic Survey of Georgia has issued a bulletin of 229 pages, descriptive of the pyrite deposits of that state. Georgia has more sulphuric acid plants than any other state and has used small quantities of local pyrite for many years, ninety thousand tons being mined annually. This is highly important in regard to the fact that two companies—the Freeport Sulphur Co. and the Union Sulphur Co.—produce all the sulphur in this country, price data on which is given in the *Official Bulletin* of June 29, 1918, as follows:

The cost of the Freeport Co. in 1917 was \$6.15 per ton; in 1918 it is estimated that increases will bring the cost up to not over \$9.50 per ton. In the first half of 1917 the Union Co.'s costs were \$5.73 per ton. The average realization of the Union Co. in the first half of 1917 was \$18.11 per ton, making a margin of \$12.38 per ton. The manufacturers of sulphuric acid are paying in the neighborhood of \$25 per ton, and some as high as \$35 per ton, making margins of over \$15 per ton for sulphur companies. The Freeport Co.'s balance sheets show an operating profit for the eleven months ending October 31, 1917, of \$4,301,310, or 236 per cent on investment. On November 30, 1916, the company's balance sheet shows dividends declared of \$925,000; on July 31, 1917, \$1,850,000; and October 31, 1917, \$2,600,000. Its surplus increased from \$1,254,000 in November, 1916, to \$2,543,000 in October, 1917.

These two companies have been to considerable patent litigation expense. Recently the Government took over the control of their operations so as to prevent a shortage of sulphur.

## War Department Centralizes Purchasing Control

ORGANIZATION of the centralized purchasing scheme whereby the General Staff controls the buying of all commodities and supervises all contracts for the Army is rapidly progressing. Already assignment of purchases of a number of commodities has been made to the several branches of the War Department, and boards of review are passing on all contracts in order to insure uniformity of contract control and provisions. The general administration of the scheme is under the direction of Brig. Gen. Hugh S. Johnson, head of the purchase and supply branch of the division of purchase, storage and traffic of the General Staff of the Army.

In the past the various branches of the department have been buying their respective commodities through their own purchasing agencies, often bidding against one another for the same goods and frequently paying several different prices for the same article. The General Staff brought together a committee of representatives of the various purchasing agencies, and this committee is now engaged in standardizing the commodities needed and assigning to one branch of the department the purchase of each commodity. This standardization has progressed to the point indicated in the accompanying list, which shows the name of the branch intrusted with the purchase of about 150 items so far agreed upon. Others are being added to the list each day:

Quartermaster: Automobile drive, chain, iceboxes, bur-lap, non-skid chains, cotton cloth, cotton goods, cotton rope, silk fabric, rubber goods, woolen rubber goods, jutes, leather, linen, manila rope, needles, woolen goods.

Construction: Reinforcing bars, cement, clay products, electrical equipment and supplies, electric wire for heavy power, refrigerating equipment, sand and gravel, rough hardware, heaters, room heating equipment and supplies, plumbing equipment and supplies roofing material sprinkler systems, ventilating equipment, water supply equipment and fixtures, structural steel.

Ordnance: Chrome and ferro-manganese alloys, ammonium nitrate, artillery chain, barometers, dry batteries, blast furnace and steel mill products, cartridge cloth, coal gas products, coal tar products, cotton lint, forging equipment, hull fiber, flash lights, dry cell lanterns, nitrates, tin, pig tin, plate tin, platinum, sodium nitrate, stop watches.

Engineers: Arc search lights, chain, paint containers, gantry cranes, locomotive cranes, paint driers, electric gas generator sets, enamels, gas engines, mechanical rubber goods, japans, lacquers, mineral spirits, paint, steam shovels, turpentine, varnishes, linseed oil, railway equipment.

Signal: Electric wire, radio equipment, telephone and telegraph equipment.

Aircraft production: Aeroplanes, cable, clocks, aviators' clothing, compasses, wood distillates, gages, oil, air and gasoline, steel hangars, linen fabric for balloons and aircraft, thermometers, spar varnish.

Medical: Surgical dressings, surgical needles, medical thermometers.

Chemical and War Gas. Elastic tape, horse masks.

Thus, ferro-alloys or ammonium nitrate, regardless of their use or of the branch that uses them, are purchased by the Ordnance Division according to specifications laid down by that division. Any other branch requiring these articles makes a requisition on the Ordnance Division for the required amount. More than 70 per cent of the articles bought by the department are now being purchased under this system.

It has been decided by the Superior Board of Review of the General Staff that, wherever possible, fixed price

contracts shall be used in the purchase of supplies for the War Department. In the exceptional cases, where it is clearly to the advantage of the Government that a cost plus contract be used, a cost plus fixed compensation contract is to be made, rather than a cost plus percentage contract.

## Federal Regulation of Common and Skilled Labor

ON AUGUST 1 the supplying of war industries with common labor was centralized in the U. S. Employment Service of the Department of Labor, and all independent recruiting of common labor by manufacturers having a payroll of more than 100 men was diverted to the U. S. Employment Service.

While the restrictions against the private employment of labor apply only to common labor at the present time, these restrictions will, as soon as possible, be extended to include skilled labor. In the meantime, recruiting of skilled labor for war production will be subject to federal regulations now being prepared. This drastic change in the nation's labor program has been found necessary in order to protect the employer and the employed, to conserve the labor supply of the communities and to cut down unnecessary and expensive labor turn-over (which, in some cases, is as high as 100 per cent a week), and to increase the production of essentials.

Under the operating methods adopted, the country has been divided into thirteen federal districts, each district in charge of a superintendent of the U. S. Employment Service. The States within each district are in turn in charge of a State Director, who has full control of the service within his State. In each community there is being formed a local community labor board, consisting of a representative of the U. S. Employment Service, a representative of employers and a representative of the employed. This board will have jurisdiction over recruiting and distributing labor in its locality.

When the survey of labor requirements has been made and the aggregate demand for unskilled labor in war work is found, each State will be assigned a quota, representing the common labor to be drawn from among men engaged in non-essential industries in that State. These State quotas will in turn be distributed among localities. Within each locality, employers in non-war work, including those who are only partially in war work, will be asked to distribute the local quotas from time to time amongst themselves. Quotas by localities and individuals are to be accepted as readily as they are for Liberty Loan and Red Cross campaigns. This plan of labor quotas is a protection for all communities. The object is to keep any community from being drained of labor, and to use local supply, as far as possible, for local demand. The situation, however, is such that in certain cases some men may have to be transported over long distances.

The War Department has finally selected the so-called Broadwell site for the half unit of the ammonium nitrate plant to be constructed by the Air Nitrates Corporation at Cincinnati, Ohio. The cyanamid process will be used as in Plant No. 2 at Muscle Shoals, Ala.

# Consumption and Conservation of Tin

THE tin consumption in the United States has increased steadily during the past decade and has been confined only by the limitations of ore supplies, a liberal sufficiency of which has never been located in the surface mineral formations of the earth. Except for the 140 tons of tin obtained near Nome, Alaska, practically the only source of tin ore supply on the American hemisphere comes from Bolivia. About 7500 tons of tin is being produced annually at the plant of the American Smelting and Refining Co. at Perth Amboy, N. J., from Bolivian concentrates, which amounts to about ten per cent of our present consumption.

The tin and terne plate industry and the solder and bearing-metal consumption, each take about one-third of our available tin. According to a statement compiled by the War Industries Board from returns obtained through the sub-committee on pig tin, the consumption of pig tin for different purposes in 1917 was as follows in gross tons:

## TIN CONSUMPTION IN THE UNITED STATES IN 1917

|                              |        |
|------------------------------|--------|
| Tin and Terne Plate.....     | 27,600 |
| Solder .....                 | 17,000 |
| Babbitt, Bearing Metals..... | 10,800 |
| Bronze and Sn-Brass.....     | 4,500  |
| Tin Foil.....                | 4,000  |
| Collapsible Tubes.....       | 2,100  |
| White Metal.....             | 1,764  |

## APPROXIMATE ESTIMATES

|                         |       |
|-------------------------|-------|
| Chemical .....          | 2,570 |
| Britannia Ware.....     | 1,500 |
| Pipes and Fixtures..... | 1,350 |

Total..... 76,257

## THE USE OF SUBSTITUTIONS

Asphalt and tar roofing have strongly relieved the demand for terne plate; paraffined or parchmentised paper cartons and glass and pottery jars have come into almost as extensive use as the tin can in food conservation; and the tin alloys, such as solder, babbitt and bronze are being thoroughly studied to bring about a satisfactory product, with a minimum tin content. In regard to these alloys, the Tin Section of the War Industries Board reports:

On account of the limited supply of tin available in the world to-day and because of the hazard involved in connection with our oversea imports upon which we depend for our requirements, and furthermore, because our war program calls for a very large tonnage of tin, it is imperative that we take immediate steps to husband our resources: First, by eliminating all waste; second, by substituting other metals wherever practicable; third, by reducing the percentage of tin used in various alloys just as far as possible, and finally, by recovering larger quantities.

The War Industries Board has conferred recently with representative manufacturers of babbitt and other bearing metals, solder and miscellaneous tin-alloy products for the purpose of explaining the present situation, and in order to obtain suggestions as to the most practicable methods for conserving tin. In co-operation with the Bureau of Standards, a number of experiments have been conducted.

The accompanying statement reports some of the findings of the Bureau of Standards resulting from their experiments and from inquiries made among a number of large manufacturers and consumers. We realize that these suggestions cover only a few means

of reducing our consumption of tin. The War Industries Board will gladly welcome others, particularly as it is expected that each recipient will be influenced in his approach to the problem by consideration of the special needs of his own line of products and manufacturing equipment. It is hoped that the very widest possible use will be permitted of any original findings that may result from a careful study of the problem.

## TIN-BASE BEARING METALS

Tin-base bearing metals are known in the trade as Babbitt Metals and are divided into three classes: 1. Tin, antimony and copper alloys. 2. Tin, antimony, copper and lead alloys. 3. Tin, copper and zinc alloys. In general they are less easily compressed than the lead-base metals. This resistance to compression is due to the relative content of antimony and copper of the bearing alloy, which are not only the hardening and wear-giving constituents but also form a crystal structured skeleton which is covered over by the soft, tough, tin bonding crystals.

Fig. 1 illustrates babbitt metal magnified to fifty diameters. The light crystal cubes are the hard grains of tin-antimony, while the needle-like grains are the

TIN-COPPER-ANTIMONY BEARING METAL

particles of antimony-copper alloy. The dark parts are the depressions in the surface due to the removal of the tin by the etching acid.

In the days of Isaac Babbitt the best known soft metal alloy was a high-grade pewter of the following composition: Copper 3.70 per cent, antimony 7.40 per cent and tin 88.90 per cent; and it was with this pewter that he initiated "babbitting" with the result that the name "Genuine Babbitt" became famous in engineering parlance. In modern practice the copper and antimony content have been increased to as high as 20 per cent, with 80 per cent tin for very hard babbitts. Many specifications now in existence call for virgin tin (Banca or Straits), where, as a matter of fact, just as good binding qualities would be obtained from a second quality pig tin with minor lead, etc., impurities. Lead has the property of lowering the melting point forming an eutectic at 36 per cent tin, but the tin should preferably be over 50 per cent, antimony not less than 12 per cent and the copper not less than 3 per cent.

Parson's white brass, which consists of 62 per cent tin, 35 per cent zinc and 3 per cent copper, is largely used for marine and automobile bearings. Its disad-

<sup>1</sup>"Chemistry of Materials," Leighton, page 187.

vantages lie in the fact that it has to be poured at red hot temperatures, is very sluggish due to the oxidized zinc skin, and has to be cast heavy, not filling into thin sections well. Perhaps the greatest and best means of conserving tin in the bearing metal industries will be to minimize the thickness and size of babbitts instead of trying to substitute extensively the tin content of the best bearing alloys with lead or zinc. At present, the designing practice is governed almost entirely by the margin of heat needed to counteract the chill during the pouring operation so that a secure bond will be obtained as well as a solid unified mass. The bearing seats are best attached by previously tinning in the presence of a soldering flux ( $\text{NH}_4\text{Cl-ZnCl}_2\text{-HCl-water}$ ) with powdered tin<sup>2</sup>. If the chill of the iron parts has been removed by moderate use of a blow lamp, very great extremes may be reached in the reduction of the thickness of the babbitts.

### SOLDERS

Over one-fifth of our tin is used in the manufacture of solders, ranging from 90 to 36 per cent tin. While the greatest care has not been used in minimizing the tin content of the alloy, most important developments have been made in preventing waste in application through the use of excessive amounts by means of electrically heated soldering irons, automatic solder-wire feeders, etc. Other metals such as cadmium have been tried as substitutes but are not of practical economic use. Perhaps electric welding and spinning operations will eventually be used more extensively, especially as tin actually becomes very scarce and costly. Fig. 2 gives the melting point curve of lead and tin<sup>3</sup>.

### DETINNING SCRAP—THE TIN CYCLE

Very many processes have been proposed for the recovery of tin from waste tin plate scrap and cans gathered by the municipal garbage systems. Ordinarily, all this class of metal is fused in a furnace

MELTING POINTS OF SOLDERS

for such castings as window weights and manufactured iron products which the brittling action of the tin does not greatly affect. Many processes for recovering the tin and solder have been tried out and some

of them were profitable at a time when tin sold for as low as 37 cents per pound. These processes<sup>4</sup> may be divided into three groups: Mechanical, chemical and electrochemical. Most interesting of these is the catalytic action of the allotropic powder form of tin, gray tin, which forms spontaneously at low temperatures and acts catalytically as a detinner at temperatures below 20°C.

The only processes in commercial operation are the low pressure dry chlorine and the sodium stannate methods. The Goldschmidt Detinning Co. recovers over two thousand tons of tin per annum by these processes, on which they hold patents. Because iron is more electro-positive than tin, methods depending on acid solvents are failures. Copper sulphate, stannic chloride, etc., will dissolve tin, but as soon as iron is exposed, the desired reaction discontinues in favor of the solution of the iron. The chlorine process fails when water is not eliminated for the same reason—HCl being formed and the iron becoming the active material. Ammonium and sodium salts of tin give a cation not active to iron and prove practical for wet processes. The handling operations are of extraordinary difficulty, and this alone probably accounts for the limited success of detinning adventures and the extensive creation of the tin cycle.

### Assets of Four Corporations for Sale

A. Mitchell Palmer, custodian of enemy alien property, has directed that the following property be placed on sale:

Berger & Wirth Company of Brooklyn, N. Y. This company was organized about 1909 under the laws of New York for the manufacture of printers' and lithographers' inks. The head office of the company is at 5860 Columbia Heights, Brooklyn. The concern was owned by Emil Worlitzer, whose residence is in Leipsic, Germany. Berger & Wirth own many valuable processes, formulas and equipment for making inks.

G. Siegle Company of Rosebank, Staten Island, New York. This company is a large importer, manufacturer and seller of colors and other chemicals. It was organized under the laws of New York, April 4, 1904. The authorized capital stock of the company is \$250,000, all owned by the G. Siegle Company, a German corporation located at Stuttgart. The plant of the company is located at Chestnut Avenue, Rosebank.

A. W. Faber, Newark, N. J. This company is the American branch of the A. W. Faber Co. of Stein, Bavaria, where it started its crayon business in 1761. It was owned by Alexander Count Faber-Castell and his wife, Otilie Countess of Faber-Castell of Stein, Bavaria. Since 1900 the offices and factory of the American branch have been at Dickerson and Hecker Streets, Newark, N. Y. The manufacture here has been limited to rubber erasers and bands. Henry Fera, Jr., has been general manager of the firm and attorney for the owners.

George Beuda Co., Boonton, N. J. This company manufactures bronze powders and is a branch of the same company at Fuerth, Bavaria, which was established in 1824. From 1905 to 1915, the company imported semifinished material direct from their German works. When the European war cut off all importation, the manufacture was continued from scrap brass.

## Cleveland Meeting, American Chemical Society

Secretary Parsons announces that the fifty-sixth general meeting of the American Chemical Society will be held at Cleveland, Ohio, September 10 to 13, 1918. A council meeting will be held on the afternoon of September 9, and the council will be entertained at dinner at the University Club by the Cleveland Section. On Tuesday there will be a general meeting at the Hotel Statler, which is to be headquarters. A dinner will be given in the evening at the Statler Hotel, followed, after a convenient interval, by a smoker at the same place. Divisional meetings will be held on Wednesday morning and all day Thursday. On Wednesday afternoon trips will be taken, probably as follows:

A—Sanitary trip. Sewage disposal experiments. Water filtration. Garbage disposal.

B—Steel industries. Blast furnaces, by-product coke, steel, Bessemer, and open hearth.

C—Industrial tour of Cleveland, including all the manufacturing centers, but only a few stops.

D—Trip by special cars to Oberlin.

In the evening the President's address will be given and this will be followed by a reception at the Hotel Statler.

After the divisional meetings on Thursday, automobile trips will be taken to one of the country clubs for dinner and to the Cleveland Museum of Arts. On Friday a special excursion is planned for Akron, Ohio, where there are interesting rubber, pottery, soda, match, and other factories. Luncheon will be served in Akron and the party can leave for home from that city.

The Cleveland chemists are arranging special entertainment, not only for the men but for the ladies who may be present, and every effort is being put forth to make the meeting a success.

Special symposia are being arranged by the chairman and secretaries of divisions and it is believed that an unusual opportunity will be given in these active chemical times for chemists to get together and exchange views and ideas, many of which cannot at present be published.

## Excess Sulphuric Acid in Britain

After a year's consideration, a governmental committee makes the following recommendations for providing an outlet for the surplus acid to be expected on cessation of hostilities, according to the *British Board of Trade Journal*: Every possible step should be taken to extend the use of fertilizers. Farmers should be educated by lectures, demonstrations and experimental plots. Cheap freights should be arranged. A joint committee of zinc smelters, acid and fertilizer makers should endeavor to introduce Government-made acid to the market so as to produce a minimum of disturbance and to suggest means whereby the erection of new acid works to deal with the gases from zinc concentrates can be avoided. The following recommendations for the relief of present owners are made: that for the purposes of taxation, the rate of depreciation on acid plants should be increased to at least ten per cent, retroactive to Jan. 1, 1915; that a government committee determine a method of scrapping old plant,

government compensation to be paid on the basis of the value as a going concern, less scrap value; and that a reasonable rate of interest be allowed on plants which should be closed rather than scrapped. General recommendations of special interest to chemists are:

(a) In view of the importance of scientific control of chemical operations, we desire to draw attention to the need for improving the status of the technical chemist.

We consider that it is essential to the success of the chemical industries of the country that the value of men of liberal education who have specialized in chemistry and its cognate sciences and have experience of manufacturing operations should be more adequately recognized.

(b) We further recommend that the very complete data as to costs of production in acid manufacture and other chemical processes obtained by the Department of Explosives Supply during the war should be given as wide circulation as possible throughout the chemical trades, with a view to encouraging the more general adoption of a more systematic study of manufacturing costs.

## Heyden Chemical Works Seized by Alien Property Custodian

The second largest corporation of its kind in the United States was seized by the Alien Property Custodian when on July 29 he took over the Heyden Chemical Works at Garfield, N. J. It is claimed that the real owner of the business was *Chemische Fabrik von Heyden* of Germany, and that the true ownership was misrepresented or concealed. The following have been appointed officers and directors of the company: President, Leroy Baldwin, President Empire Trust Company, 120 Broadway; Vice President, James A. Branegan, chemist, 1421 Chestnut Street, Philadelphia; Secretary, F. N. B. Close, Bankers Trust Company, 16 Wall Street; Counsel, J. Harry Covington, former Chief Justice of the Supreme Court of the District of Columbia, and Royal H. Weller, ex-Assistant District Attorney, of 31 Nassau Street, New York.

## Chemists in France

Another tie joins France and American with the recent establishment of a French local section of the American Chemical Society.

Application has been made and granted for permission "to found in Paris a French section of the society covering the entire territory of France." The signatures on the application are those of distinguished French chemists intermingled with these of American chemists, who are now at the front in the service of our army. It is a joint brigading of French and American forces somewhat similar to that which has been affected recently between units of the respective armies. The successful result of the military union has already made itself evident on the battlefields of France and corresponding results can be predicted from this union of scientists.

## Koppers Company Stock For Sale

Custodian of enemy alien property, A. Mitchell Palmers offers for sale the stock owned by Heinrich Koppers of Essen, Germany, in the H. Koppers Company of Pittsburgh, which does a large business in designing, building and operating by-products coke ovens. The company is capitalized at \$1,500,000 and it is reported that 20 per cent of the stock will be sold.

## The Sexagesimal Trade Units

Factors and Factor Interrelations of Gallons,  
Pounds, Cubic Feet, and Gravities

SINCE the international introduction of the C. G. S. system of units 67 years ago, men of scientific training in the United States and Great Britain have sought to have our ancient trade units superseded by this more mathematically convenient system, which was so gloriously installed by the French at the time they cast out king and royalty, removed the spell of antiquity and thus started an age of scientific development in every field of the mental environments of mankind. The origin of the English trade units are buried deep in an unwritten history of the early commercial navigators. The pound undoubt dly came from the Roman *libre*, as a consequence of the military colonization of England by the Romans.

The numerical foundation of these trade units as a whole can well be called astronomical—the sexagesimal system was very popular with the star-gazers of Egypt, not only because of having the factors 1, 2, 3, 4, 5 and 6, but also because they expected to find some ultimate mathematical relationship between these numbers and the movements of the heavenly bodies. The lore of the astronomer had its economic value as well, perhaps, as its origin and development in guiding the traveler on the starlit sands of the Sahara and finally over sea and ocean. The numbers 7, 9, 11, and 13 gave these semi-magicians much trouble as they were—and are still by some—regarded with mystery. However, the ancient navigator certainly had a much wider education in the “1 to 6” multiples than we of the fingers-and-thumbs decimal age on casual thought credit him with having. For this reason, it would not be out of place to critically examine these familiar old units with the same point of view with which one would, were he transposed back to the dawn of science when the magician was closely scrutinizing the stars.

After the number 60, 12 seems to have been of greatest importance, perhaps because of the number of moons in the four seasons, perhaps also because it was devisable by all of the “1 to 6” excepting 5. The dozen became the trade count, the foot was divided into twelve parts, the medicines of the magician were divided by twelfths, and so on. What bearing the fact that 12 wine gallons of water weighs approximately one hundred pounds had to do with the origin of that unit may be left open to conjecture, as well as the fact that 60 pints equals one cubic foot; however, prior to the time of the manufacture of measuring instruments by skilled tradesmen the handy seven-inch diameter by six-inch high cylindrical container may have had some numerical origin in magical logic.

That they worked diligently compounding numbers is a well-known fact, and while they did not originate a system of units having the conveniences of the decimal C. G. S. system, nevertheless, their units were not absolutely without preconceived relation.

Most important of these relations of volumes and weights with reference to water are:

|                          |      |             |
|--------------------------|------|-------------|
| 1 cu.ft. of water weighs | 1000 | oz. avoird. |
| 1.6 “ “ “                | 100  | lbs. “      |
| 12 gal. “ “ “            | 100  | “ “         |
| 60 pints “ “ equals      | 1    | cu.ft.      |

The first relationship of ounces to cubic feet makes the solution of gas problems by Avogadro's Law as convenient with English units as with grams and litres. Thus an ounce-mol of any gas would make 22.4 cu.ft., etc. However, the C. G. S. system has taken undisputed possession of the laboratory, and it is only in trade metrology that any useful existing interrelations might prove valuable. Thus an ounce-mol of carbon dioxide, weighing 44 oz., would measure 22.4 cu.ft., as would 28 oz. nitrogen, 32 oz. oxygen, 29.2 oz. air, etc.

As the volume of 12 gallons or 1.6 cu.ft. of any substance weighs 100 times its gravity in pounds and the weight of any material to that of water is very easily determined by simple and well-known laboratory methods and for many substances is recorded in tables of specific gravities, it is easy to obtain weight per gallon or per cubic foot by pointing off the gravity two places and dividing by 12 for the former and 1.6 for the latter.

Thus if the specific gravity of a sample of  $H_2SO_4$  were found to be 1.44, the weight would be, per gallon,

$$\frac{144}{12} = 12 \text{ lb.}; \text{ per cubic foot, } \frac{144}{1.6} = 90 \text{ lb.}$$

Of course the specific gravity must be relative to water at 39 deg. F., or 62.5 lb. per cubic foot, which is approximately an average for good city water, though chemically pure water is one-quarter of one per cent lighter.

When the Baumé scales are used, the formulae employed to obtain the specific gravities would be as follows:

Lighter than water.

$$\text{Sp.Gr.} \frac{60}{60} = \frac{140}{130 + \text{deg. B}}$$

Heavier than water.

$$\text{Sp.Gr.} \frac{60}{60} = \frac{145}{146 - \text{deg. B}}$$

Thus, with a sample of 66° Baumé sulphuric acid:

$$\text{Sp.Gr.} \frac{145}{145 - 66} = 1.835$$

$$\text{Cu.ft.} = \frac{1.835 \times 100}{1.6} = 114.6 \text{ lb.}$$

$$\text{Gal.} = \frac{1.835 \times 100}{12} = 15.6 \text{ lb.}$$

By way of illustration to show the probability of the immediate introduction of the C. G. S. units into our trade, the resolution adopted by the National Association of Manufacturers at their recent convention may be noted:

WHEREAS, the agitation for the adoption of the metric system has been again revived and is being vigorously conducted, and

WHEREAS, the ‘British Committee on Commercial and Industrial Policy after the War’ has made an exhaustive analysis of this question and concludes in language as follows:

‘We are not convinced that the metric system is upon the whole even theoretically superior to the British system, and we are satisfied that the practical objections to the proposed change are such as to decisively outweigh any advantages which are claimed for it.

Therefore, be it

*Resolved*, that we regard the agitation for the establishment of the metric system as particularly untimely because of war taxation on manufacture, and because under present conditions the overwhelming activity of manufacturers in war work makes proper consideration of such a subject impossible. It is further

*Resolved*, that we endorse the work of the American Institute of Weights and Measures in opposing the adoption of the metric system.

# The Manufacture of Carbon Electrodes for Electrometallurgical Purposes\*

Raw Materials Suitable for Electrode Manufacture—Proportioning of Ingredients—Methods of Mixing and Firing—Testing the Finished Electrodes—Summary of Manufacturing Methods Used by Different Companies—Bibliography of Technical and Patent Literature

THE carbon electrode is the product of an industry which started about forty years ago. In the middle of the last century carbon plates and carbon pencils, principally as battery carbons, were made on a small scale, although manufacturing proper can only be considered to have begun about the '70's.<sup>1</sup> The credit for developing an industrial process of manufacture which is still used today in its general outline belongs to the Frenchman, Carré. In 1876 and 1877 he stated definitely the principal steps in his process: Grinding, mixing with a binding medium, pressing and afterward heating to incandescence. He introduced the idea of bedding the incandescent piece in coal dust and he was the first to manufacture artificial carbon industrially. The artificial carbons made at that time were used principally for illuminating purposes, but later they were employed for electrothermic processes. The industrial use of the electric arc in large furnaces as a source of heat, in the production of aluminium, the making of calcium carbide and ferro-alloys, as well as of electric steel, gave a great impetus to the manufacture of electrodes.

The demands made by electrothermic processes on the quality of artificial carbon are quite different from the requirements for obtaining a steady arc in electric lamps. Diffusion processes, such as making carbide and aluminium, require principally great mechanical strength, good conductivity and small losses. At the same time, the requirements in regard to dimensions were considerably greater than was the case for the manufacture of arc carbons or battery plates. This made it necessary to adjust the manufacture to the working of considerably larger quantities of material, and thus the manufacture of artificial carbon entered the circle of big industries. At the present time the

turnace installation of the large firms is of such size that it can be considered among the largest ceramic kiln installations existing. The machinery used is manifold and of quite considerable size. This is especially true of the hydraulic presses, used in the making of large electrodes.

The following notes describe the processes used in

some of the electrode factories, in so far as that is possible, following either the communications made by the respective factories or the data found in the literature. In general, the process consists in mixing the ground and cleaned raw material with tar, giving it the desired shape by pressing, and finally calcining the material to give it the required strength and conductivity. The manufacturing process is therefore in principal a very simple one, and in part is closely related to the general methods of ceramic manufacture. Whereas in the latter the binding medium is always a plastic clay, in the former the binding medium consists of pure carbon grains, the coke residue which remains after the calcination of tar or pitch-like substances.

The raw materials considered suitable for the manufacture of electrodes include all varieties of carbon found in sufficient purity and in a form which can be industrially used as such: Coke, charcoal, anthracite, lamp black, retort carbon, tar coke, petroleum coke and graphite. The proportioning of the quantities of the different ingredients and the size of the

grain are naturally of decisive importance for the quality of the final product. The manufacture begins with the crushing of the raw material in case that is necessary. As these substances are usually quite hard, it is necessary to provide extensive equipment for graded crushing, grinding and screening. Only a few of the numerous mill constructions have proved satisfactory, because the wear on the machinery is considerable if the wrong kind is chosen, and the presence of metallic iron in the smallest percentages must be avoided.

FIG. 1.—VERTICAL PRESS

\*Translation from *Stahl u. Eisen*, 32, 1912, p. 1857.

<sup>1</sup>On the historic development of the manufacture of electrodes—see Zellner: "The Artificial Carbons for Electrotechnical and Electrochemical Purposes, Their Preparation and Testing." Berlin, 1903, published by Julius Springer; further Tsch: "The Manufacture of Carbons for Electric Lighting and Other Purposes." London, 1899; *Zeitschrift für Elektrochemie*, 1901, 28, March, p. 516; *Elec. World*, 1909, v. 2, p. 682.

<sup>2</sup>See *Compt. Rendus*, v. 4; *Bull. de la Société d'Encouragement*, 1877; H. Fontaine, *L'Eclairage Electrique*, 1877.

The raw materials are subjected to calcination so as to remove all gases and oily substances. The crushed raw material is then mixed with the binding medium, tar or pitch, and kneaded. It is then given the required cross-section in a lever press as shown in Fig. 1.

The pressed pieces thus prepared are subjected to a roasting and coking process in a gas-fired angular kiln, with exclusion of atmospheric air. The kilns shown in

The process and installation of the Soc. Am. Electro-metallurgic Procédée Paul Girod, Ugine, are as follows: The principal raw products used by this firm for the manufacture of electrodes are: (1) Retort carbon; (2) petroleum coke; (3) anthracite. Pitch is used as a binding medium. These various raw products are used either separately or mixed in certain proportions, their selection depending upon the cost of production.

FIG. 2.—KILNS FOR BURNING ELECTRODES

Fig. 2 are generally low furnaces constructed of the best refractory material in order to withstand continuous temperatures of 1500 to 1600 deg. C. The exclusion of air is accomplished by placing the electrodes into square or round chambers of very refractory material and filling the space between electrode and chamber wall with carbon dust. The chambers are fitted with airtight covers. The period of calcination varies according to the dimensions of the electrode, being from six to twelve days for the smaller pieces and from ten to sixteen days for the larger ones. The firing must be extraordinarily uniform as otherwise stresses occur in the electrodes which easily lead to the formation of cracks.

During the first period of the calcination process the tar oils contained in the binding medium distill off, continuing up to the moment that red heat begins. Then the binding medium begins to coke and finally the whole mass begins to slag. The finished electrodes are removed from the furnace, and after complete cooling are examined for cracks or other faults, after which they are ready for use.

A German factory gives the following values for the physical and chemical qualities of amorphous carbon electrodes:

|                                                                            |                            |
|----------------------------------------------------------------------------|----------------------------|
| Specific weight                                                            | 1.50-1.55                  |

Retort carbon comes, as is well known, from obstructions formed in the retorts of gas plants. The ash varies from 1 to 3 per cent and contains little volatile substance. After its incineration, only small traces of ash are found and consequently this material can be used directly for the manufacture of electrodes without

FIG. 3.—RETORTS FOR DISTILLATION OF PETROLEUM COKE

preliminary treatment. Analysis of retort carbon is approximately as follows:

|                    | Per Cent |
|--------------------|----------|
| Ash...             | 1.77     |
| Volatile matter... | 0.46     |
| Sulphur            | 0.73     |

Petroleum coke, however, is different. This is a residue obtained from the distillation of heavy oils or petroleum oils, and still contains from 5 to 8 per cent of

\*On the raw materials for electrode manufacture; see also Zellner, *Stahl u. Eisen*, v. etc., p. 19-84.

volatile hydrocarbon. Hence it requires a special treatment consisting of further distillation before it can be used in the manufacture of electrodes. This distillation is carried out in furnaces with horizontal retorts similar in construction to the ovens used in gas plants (Fig. 3). Petroleum coke is heated in these retorts for about 6 hours at a temperature of 1000 deg. C., after which it contains only about 2 per cent of ash. In addition to

Anthracite is treated in about the same manner as petroleum coke because it also contains volatile matter. Its ash content amounts to about 2 per cent. The selection of the anthracite is more difficult than in the case of the two previously mentioned materials, because it is found to contain a strong admixture of iron oxide which is detrimental for the purposes to which the electrodes are applied. The composition of the anthracite used is ordinarily as follows:

|                           | Per Cent |
|---------------------------|----------|
| Ash .....                 | 2 77     |
| Volatile substances ..... | 6 30     |
| Sulphur .....             | 0 79     |
| Phosphorus .....          | 0 032    |
| Iron oxide .....          | 0 27     |

After these materials have been treated for the removal of volatile matter they are passed through a crushing and grinding plant and broken into grains of a size between 2 and 3 mm. They are then packed into sacks and weighed and are ready for the manufacture of electrodes.

The tar which serves as a binding medium is a mixture of pitch and tar oil, the quantity ratio of which must be kept exactly. It usually has the following composition:

|                       | Per Cent |
|-----------------------|----------|
| Ash .....             | 0 15     |
| Volatile matter ..... | 43 0     |
| Carbon .....          | 56 85    |

The composition of this tar is determined by two methods, both of which are of equal value and can therefore be used as checks. According to one method the volatile constituents and the ash and carbon contents are determined. According to the other the viscosity is measured, by determining the time required by a certain quantity of the tar to flow through a circular opening of known dimension.

The raw materials are then mixed in a steam jacketed mixing apparatus. The quantity of tar used varies between 22 and 30 per cent, depending upon the manufacturing process, i.e. if the electrodes are to be pressed or squirted out by a special press.

When the mass is sufficiently mixed it is further worked in mills as shown in Fig. 4, so that it becomes very dense. It is then put into the first press, shown in Fig. 5. Here it is pressed in a cylindrical container and has the shape of a block when freed from its mold. Such a block weighs approximately 1200 kg. After leaving the stamp press the block enters another special squinting press, shown in Fig. 6, where it is molded under pressure of from 380 to 400 kg. per sq. cm'. The extruded blocks will furnish from four to eight electrodes of the required diameter.

After leaving the special press the electrodes are set into an annular kiln, shown in Fig. 7, where they are embedded in coke dust in a vertical position in special earthen vessels. The calcination results in the distilla-

FIG. 4.—MILLS FOR WORKING RAW MATERIAL

this supplementary distillation, petroleum coke is subjected to a preliminary washing for the purpose of removing any soluble salt which it may contain. This work is carried out in chambers of 140 cu.m. capacity, there being six of these chambers at the plant. They are charged with coke and each of them is completely filled with water two or three times in succession so as to leach the soluble salt.

FIG. 5.—PRESS

The composition of petroleum coke is approximately as follows:

|                           | Before Washing,<br>Per Cent | After Washing,<br>Per Cent |
|---------------------------|-----------------------------|----------------------------|
| Ash .....                 | 3 09                        | 2 83                       |
| Volatile substances ..... | 6 55                        | 5 45                       |
| Sulphur .....             | 1 44                        | 1 34                       |
| Chlorine .....            | 2 36                        | 0 52                       |

\*On the mechanical working of carbon, crushing, mixing, pressing, see Zellner, p. 85-173.

tion of the volatile portion of the tar used as a binding medium, and the remaining carbon combines with the original grains to form the electrode.

The kiln consists of about thirty chambers, each with six vessels. It is heated by gas furnished by two gas

berg, describes electrode manufacture as follows:\*

The raw material, which is retort graphite from gas plants, is carefully freed from all impurities by brushing. For that purpose the pieces, often weighing hundreds of pounds, are crushed in rock crushers into pieces

about the size of the fist. They are then heated with exclusion of air to 1200 deg. C. so as to completely expel all volatile components. The pieces are then ground very fine and the powder is screened to uniform grains of the finest size, because it is of the utmost importance in the manufacture of electrodes that only very fine material should be used. The powder, free from dust, is very carefully mixed with tar, freed

FIG. 6.—HORIZONTAL EXTRUSION PRESS

producers and is maintained at a constant temperature, rising from about 1100 to 1250 deg. C. It is of the utmost importance that the heating of the chambers should be regular and progress uniformly. The same is true as regards cooling. Any deviation from this rule means a failure in the product.

The results of analyses of the producer gas and the product of combustion in the kiln were as follows:

|                                                | Test I | Per Cent<br>Test II | Test III |
|------------------------------------------------|--------|---------------------|----------|
| At exit from gas producer:                     |        |                     |          |
| CO <sub>2</sub> .....                          | 4.5    | 6.3                 | 3.9      |
| O .....                                        | 2.2    | 2.3                 | 6.9      |
| CO .....                                       | 25.0   | 22.8                | 21.7     |
| Combustion product of gases at exit from kiln: |        |                     |          |
| CO <sub>2</sub> .....                          | 12.1   | 12.4                | 13.8     |
| O .....                                        | 5.8    | 6.0                 | 5.4      |
| CO .....                                       | 0.4    | 0.4                 | 0.0      |

It will be seen that products of combustion contain a small surplus of oxygen. It is very difficult to keep all of the openings airtight, especially if the kiln has been used for some time. The combustion of the gases in this case was evidently good, as the carbon monoxide content never exceeds 0.4 per cent.

After removal from the kiln the electrodes are brushed and examined. They must show no cracks and when tested by striking with a hammer must give a clear, pure tone.<sup>5</sup>

Some of the electrodes from each batch are taken for test and are examined for resistance in the test machine. Hitherto those tests were made by means of a milli-ampere meter, but that apparatus is too sensitive and is better suited for laboratory than for industrial purposes. The results obtained by this method were often impaired by intermediate resistances, as only weak currents were passed through the electrodes. It became necessary, therefore, to devise a machine which permitted of working with greater current and which yielded more exact and more uniform results.

The electrode factory of Dr. Albert Lessing, Nurn-

berg, describes electrode manufacture as follows:\*

The raw material, which is retort graphite from gas plants, is carefully freed from all impurities by brushing. For that purpose the pieces, often weighing hundreds of pounds, are crushed in rock crushers into pieces about the size of the fist. They are then heated with exclusion of air to 1200 deg. C. so as to completely expel all volatile components. The pieces are then ground very fine and the powder is screened to uniform grains of the finest size, because it is of the utmost importance in the manufacture of electrodes that only very fine material should be used. The powder, free from dust, is very carefully mixed with tar, freed from water, and heated for several hours in mixing machines, after which it is allowed to stand for some time. The shape of the electrode is given, according to the installation of the plant, either in large stamping machines which press the material into the required form in the cylinders of the electrode press, or in these same cylinders the mass is compressed by hydraulic means. It is necessary to envelop the cylinder with a steam jacket because after cooling of the tar the mass is quite stiff and not very pliant. It is, therefore, necessary to heat the mass throughout to about 40 deg. C. When this temperature has been reached, a mouth-piece is fitted to the open end of the cylinder which has an aperture exactly corresponding to the shape of the electrode, with  $\frac{1}{2}$  per cent added on account of the shrinkage during the further working of the mass. The electrodes thus compressed under the highest pressure are left for several days exposed to the air, after which they have hardened so much that they can be handled quite freely without breaking.

The electrodes are then placed in large kilns of the annular kiln type, situated underground so as to avoid the heat losses. Here begins the most difficult part of the manufacture, namely, the calcination at a temperature of 1300 deg. C. During this treatment the greatest care has to be taken, and in the best factories fourteen days are required for gradually heating the electrodes up to the maximum temperature and for the cooling which follows. The following reasoning shows how important it is to heat the material slowly. Carbon is a poor heat conductor. If the heating proceeds rapidly the outer layers will have been burned hard while the inner core will not have been sufficiently heated. The purpose of the calcination is to remove the tar which was previously added to increase the plasticity of the material. With too rapid heating, the tar in the interior would distil later and destroy the outer crust.

\*On the process of calcination (roasting), kiln, and kiln management, see also Zellner, p. 174-204.

"Zeitschrift für Elektrochemie," 1903, 26, March, p. 260.

It is necessary to examine the carbon carefully to detect large cracks. Small cracks on the surface only, so-called fire cracks, are of no importance. A flawless electrode, calcined to the core, should give a full sounding, clear, strong note when tapped with a hammer, whereas an electrode with cracks will have a sound like a broken pot.

The electrical resistance of such electrodes must be within narrow limits. It does not exceed 400 ohms per sq.mm., and 1 m. in length with the heaviest pieces, and with increasing cross-section it falls to 80 and 100 ohms. For many purposes the great chemical purity is of importance. On the other hand, small quantities of ash are of no importance in electrodes used in the manufacture of calcium carbide, since the raw materials, lime and coal, carry proportionately larger quantities of impurities into the finished product. It is evident also that the very pure electrodes are correspondingly expensive.

Clacher<sup>1</sup> has described the manufacture of electrodes in the factory of the British Aluminum Co. at Greenock, Scotland, as follows:

1. The petroleum coke is roasted to remove all volatile substances and increase its density and conductivity.
2. The roasted material is crushed.
3. The crushed material is mixed with a binding medium in a steam-heated mixer.
4. The mixed mass is shaped.
5. The block is calcined in a kiln which requires five days; after cooling the blocks are brushed and placed in the warehouse ready for delivery.

The petroleum coke contains from 5 to 13 per cent volatile hydrocarbon which escapes in the process of distillation; it contains further a small quantity (about 2 per cent) of inorganic substance. It is usually furnished by the oil plant in pieces of large dimensions, which is of great advantage, as the small coke and dust always present easily clog the roasting kilns, and thus only a small quantity of them can be used in a charge.

The kilns are arranged vertically, the coke being charged on top and the calcined material removed at the bottom. Charging is done every two hours, and each half hour a charge is removed, the coke requiring five hours to pass from the throat to the bottom. The temperature of the kiln at its hottest part reaches about 2000 deg. C. The process is very expensive with the method used at present, since 30 per cent of the coke charge is completely consumed. The volatile components of

the coke before calcination amount on an average to 8 per cent, so that 22 per cent of carbon is consumed to raise the temperature up to 2000 deg. C. The roasting was also done in horizontal retorts, the first cost of installation of which is greater, but the operation of which is more economical, the loss amounting to only 20 per cent. When the calcination was done in a flow of producer gas, the loss was somewhat higher than the percentage in volatile components of the material; the loss was 15 per cent with 10 per cent of volatile substances in the coke. The temperature is not so high as in the vertical retorts and does not much exceed 1000 deg. C.

After calcination the coke at Greenock contained 0.7 per cent of inorganic substances, as follows:

|                        | Per Cent |
|------------------------|----------|
| Silicic acid           | 0.50     |
| Iron oxide and alumina | 0.15     |
| Soluble sodium salt    | 0.05     |

The calcined coke is first crushed until the material all passes through a 9.5 mm. screen, after which it is ground to the exact powder grain size. This grinding is of the utmost importance. The quantity of fine and coarse grained powder must be in suitable proportion, so as to give a block of the highest density and least porosity. The following is a good mixture: 40 per cent of material screened through a 100-mesh screen; 15 per cent of material through a 60-mesh screen; 20 per cent through 30-mesh; 15 per cent through a 16-mesh, and 10 per cent through a screen of 8 to 16 mesh. The crushing is done in stone crushers and rapid running vertical mills. The cost of crushing at Greenock amounted to from 75c. to \$1 per ton.

The following raw materials are used at Greenock:

1. The residue blocks of the aluminium ovens which contain about 2 per cent of inorganic matter, of which a little more than 1 per cent is silicic acid and iron oxide. These blocks are crushed in the usual way to the grain size of an 8-mesh screen. The composition of the material is as follows:

FIG. 7.—ANNULAR KILNS FOR CALCINING ELECTRODES

## The Determination of Copper in Insecticides\*

BY GEORGE S. JAMIESON

THE separation of copper as cuprous thiocyanate and its titration with a standard solution of potassium iodate in the presence of hydrochloric acid using an immiscible indicator such as chloroform as described by Jamieson, Levy, and Wells,<sup>1</sup> has been successfully applied to the estimation of copper in Bordeaux and Paris Green insecticides. When lead is present, it is necessary to remove it as the sulphate before proceeding to precipitate the copper. However, it has been found that arsenic did not interfere with the method.

The potassium iodate solution used in this investigation contained 11.7840 gr. of potassium iodate in 1000 cc. One cubic centimeter of this solution corresponded to 0.002000 gr. of copper. The reaction between the cuprous thiocyanate and the potassium iodate is represented by the following equations:

From 0.2 to 0.5 gr. of insecticide, depending upon the amount of copper present, was weighed into a No. 2 beaker. The powder was thoroughly moistened with about 10 cc. of water. About 5 cc. of sulphuric acid (1:3) was added and the solution was warmed to facilitate the decomposition. It was observed in some cases that a small amount of difficultly soluble material remained even after heating. No attention need be paid to this, as it caused no interference with the accuracy of the method. When the sample was completely decomposed, the larger part of the free sulphuric acid was neutralized with (1:1) ammonium hydroxide.

The solution which should now have a volume of 30 to 40 cc. was heated almost to boiling and treated with 10 cc. of strong sulphur dioxide water. Then 5 to 10 cc. of a 10 per cent solution of ammonium or potassium thiocyanate was added and the solution was stirred for 2 minutes. The precipitate was allowed to settle for 15 minutes before filtration. The cuprous thiocyanate may be filtered either on a close filter paper or on asbestos in a Gooch crucible as preferred. The precipi-

tate is washed with warm water until the soluble thiocyanate is removed. Owing to the slight solubility of the precipitate, care should be taken to avoid excessive washing.

Sometimes the cuprous thiocyanate will run through the filter. In such cases continue the filtration until the filter has become clogged and the filtrate is running clear, then refilter. No further trouble will be experienced.

The filter containing the precipitate is carefully removed from the funnel and folded so as to slip readily through the neck of the 250 cc. glass-stoppered bottle. Care should be taken not to occasion loss by allowing the fingers to come into contact with the precipitate. The precipitate adhering to the upper edge of the funnel or the Gooch crucible, the stirring rod, and the beaker is removed with small pieces of filter paper which are added to the titration bottle. A mixture of 35 cc. of concentrated hydrochloric acid and 20 cc. of water along with 7 cc. of chloroform are added. After each addition of potassium iodate solution, the stoppered bottle is thoroughly shaken. The rapidity with which the iodate solution may be added can be judged from the color changes of the aqueous solution and the chloroform. When the larger part of the iodine has disappeared, the titration should be continued carefully so as not to overtitrate the solution. The end point is the disappearance of the violet color from the chloroform. In order to prevent the hydrolysis of the iodine monochloride it is important to have a concentration of at least 10 per cent of hydrochloric acid in the solution at the end of the titration. According to the directions given above, enough hydrochloric acid is present so that 50 cc. of the iodate solution may be safely used without unduly lowering the acid concentration. For comparison the copper in the insecticides studied was determined by the thiosulphate method<sup>2</sup>.

The following results were obtained:

| Insecticide                   | Gr. Taken | Cc. of KIO <sub>3</sub> Used | Cu Found, Per Cent | Cu by Thiosulphate, Per Cent |

These test analyses show that the iodate method gives very satisfactory results. In view of the advantages that this method has over the thiosulphate procedure<sup>3</sup> it can be highly recommended for the determination of copper in insecticides.

## Ilsemannite\*

### Results of a Study of a Blue, Water-Soluble Molybdenum Compound Occurring in Utah—Methods of Analysis and Results of Extraction Tests

By H. F. YANCEY

A DEPOSIT of considerable size of a molybdenum ore partially soluble in water has been found recently near Ouray, Utah. The ore is a sandstone containing the blue mineral ilsemannite. About one-half of the molybdenum in the ore is soluble in water, giving a deep blue solution. The geological features of this deposit have been investigated by Frank L. Hess of the U. S. Geological Survey; while Waldemar T. Schaller, also of the Survey,<sup>1</sup> has presented a preliminary report on the mineralogical aspects of the mineral.

In the present paper, the results of a brief study of the water-soluble blue compound are given, together with some results obtained in extracting the molybdenum from the ore. As ilsemannite is a comparatively rare mineral, very little is found in the literature regarding methods of extraction.

The blue ore found near Ouray, Utah, first attracted attention because of its property of giving a very deep blue color to water. Samples submitted to various assayers by a development company brought the report that it was without value. Because of the intense blue color of the water-soluble portion of the ore, this company thought that the blue solution might possibly be used as a dye. The company submitted samples to a dye-house which reported that the ore contained "molybdenum blue," an artificial compound sometimes used as a dye, and that the specimens sent them were probably "faked," as "molybdenum blue" was unknown in nature.

#### EARLY REPORTS ON ILSEMANNITE

Ilsemannite, a natural "molybdenum blue," was first reported as occurring at Bleiberg, Carinthia, by Hoefer in 1871,<sup>2</sup> who gave to it the name ilsemannite for J. C. Ilsemann (1727-1822), a German mining commissioner. It has also been reported by Lindgren and Ransome<sup>3</sup> as occurring in the Cripple Creek District, Colorado, and at Natal, South Africa, by duToit.<sup>4</sup> Horton<sup>5</sup> reports the occurrence of a molybdenum mineral having similar properties near Idaho Springs, Colorado.

The analysis of an air-dry sample from 90 pounds of the ore for the ordinary constituents gave the following results:

|                                              | Per<br>Cent |
|----------------------------------------------|-------------|
| Silica, SiO <sub>2</sub>                     | 65.92       |
| Total Iron as Fe <sub>2</sub> O <sub>3</sub> | 4.35        |
| Alumina, Al <sub>2</sub> O <sub>3</sub>      | 12.27       |
| Titania, TiO <sub>2</sub>                    | 0.35        |
| Lime, CaO                                    | 1.36        |
| Magnesia, MgO                                | 0.50        |
| Molybdenic Oxide, MoO <sub>3</sub>           | 1.22        |
| Total Soluble as SO <sub>3</sub>             | 11.00       |
| Moisture                                     | 1.11        |
| Loss on ignition                             | 4.80        |

The material evolves hydrogen sulphide with dilute hydrochloric acid, and when heated in a closed tube it gives voluminous fumes of sulphur dioxide. Vanadium and lead are entirely absent, or present only in minute traces. Large pieces of the ore have a blue-gray color. A small amount of material resembling mica is present.

#### CONSTITUTION OF ILSEMANNITE—HISTORICAL

The formula for ilsemannite generally given is MoO<sub>3</sub>.4MoO<sub>3</sub>. This formula was first given to a synthetic blue molybdenum compound by Berzelius. Hoefer<sup>2</sup> in naming a similar blue molybdenum mineral, ilsemannite, gave to it the formula of Berzelius, because the compound which was found in nature possessed similar properties. Various investigators have assigned different formulae to the synthetic molybdenum blue compound, but Guichard<sup>7</sup> in an exhaustive investigation has conclusively shown the formula to be MoO<sub>3</sub>.4MoO<sub>3</sub>, for the oxide anhydride, and the same formula with six molecules of water for the hydrate of the oxide. Several months after the publication of Guichard's paper, Bailhache<sup>8</sup> prepared two blue molybdenum molybdates by the interaction of the sulphate of the sesquioxide Mo<sub>2</sub>O<sub>3</sub>.2SO<sub>3</sub> with normal barium molybdate BaMoO<sub>4</sub>, and with barium heptamolybdate Ba<sub>7</sub>Mo<sub>7</sub>O<sub>41</sub>. The blue molybdates formed have the composition Mo<sub>2</sub>O<sub>3</sub>.2MoO<sub>3</sub>.6H<sub>2</sub>O, and (Mo<sub>2</sub>O<sub>3</sub>)<sub>3</sub>.(Mo<sub>2</sub>O<sub>3</sub>)<sub>4</sub>.18H<sub>2</sub>O respectively. Bailhache also states that it is possible to obtain other blue molybdates by the action of each of the series of barium molybdates on "molybdyle" sulphate, MoO<sub>3</sub>.2SO<sub>3</sub>. Guichard<sup>7</sup>, in a later paper, considers the method of preparation of the blue oxide by Bailhache and Klason<sup>9</sup> as interesting, but believes them to be identical with MoO<sub>3</sub>.4MoO<sub>3</sub>.6H<sub>2</sub>O.

Very few workers have investigated the constitution of the blue molybdenum compound occurring in nature, the mineral ilsemannite. As previously stated, Hoefer named the mineral ilsemannite, and gave to it the formula of the synthetic molybdenum blue of Berzelius. Muthmann<sup>10</sup> did not accept the formula of Hoefer for the mineral, stating that ilsemannite is MoO<sub>3</sub>.2MoO<sub>3</sub>. Schaller<sup>11</sup>, however, considers ilsemannite as a hydrous sulphate of molybdenum of the formula MoO<sub>3</sub>.SO<sub>3</sub>.5H<sub>2</sub>O, and suggests that this "formula be taken until further quantitative analysis on pure material shows a difference." Schaller also states that the water-soluble portion of the ore contains iron sulphate, and that the consumption of permanganate in titrating this solution exactly equals

<sup>12</sup>Loc. cit.

the amount of iron (as ferrous iron), determined gravimetrically, and also that the intense blue color of the water-soluble portion is due to an undeterminable trace of molybdenum dioxide,  $\text{MoO}_3$ .

Confirmation of a portion of Schaller's work, particularly with respect to the amount of molybdenum in the reduced condition, and to the presence of molybdenum sulphate, has been impossible. Instead of finding an undeterminable trace of molybdenum dioxide, a sample from the same deposit shows as much as 12.5 per cent of the total molybdenum present to be in the reduced condition, assuming it to be present as molybdenum dioxide ( $\text{MoO}_3$ ). Schaller considers ilsemannite to be a hydrous sulphate of molybdenum, basing his formula on incomplete analysis of the water-soluble portion of the ore. It has been found that a somewhat more complete analysis of the water-soluble portion of the ore does not show the presence of sufficient sulphuric anhydride to combine with any of the molybdenum if the iron, aluminium, calcium and magnesium are assumed to be present as sulphates.

Schaller considers the intense blue color of the water-soluble portion of the ore to be due to an undeterminable trace of  $\text{MoO}_3$ , which he considers as having a very high coloring power. Ullik<sup>12</sup> in 1867 prepared impure molybdenum dioxide having a blue color in the crystalline form. The pure oxide according to later investigators is not blue, but brown or violet brown.<sup>14</sup> Muthmann<sup>15</sup> obtained pure molybdenum dioxide in opaque crystals having a violet reflex which were insoluble in boiling hydrochloric acid and caustic potash. It is, therefore, improbable that molybdenum dioxide is itself soluble in water, and that the blue color of the water-soluble portion of the ore is due to molybdenum dioxide alone. However, molybdenum dioxide is blue when in combination with the trioxide in the form of a double oxide or molybdenum molybdate; but the presence of only a trace of a lower oxide in combination with its equivalent of the trioxide is not enough to account for the blue color of the water extract of the ore.

#### DETERMINATION OF REDUCED MOLYBDENUM

The selection of a method for determining the quantity of molybdenum in the reduced condition in the water-soluble portion of the ore presented many difficulties. This is true because the water extract contains ferrous iron as well as reduced molybdenum. The blue molybdenum compound present is easily oxidized by the ordinary oxidizing agents. A reagent which would oxidize the iron without oxidizing the molybdenum could not be found. A solution of ferric iron oxidized the reduced molybdenum, and was most promising, but the reaction did not apparently proceed to completion until the addition of a considerable excess of ferric iron. Again, the oxidation of the reduced molybdenum by ferric iron is somewhat slow. It was then considered advisable to find a method of separating the iron in the water extract of the ore from the blue molybdenum compound. Ninety-five per cent alcohol dissolved the blue material of the ore, but at the same time also dissolved the ferrous iron. Absolute alcohol was next tried, but this would dissolve only a very small amount

of the blue compound and some ferrous iron. Guichard<sup>16</sup> states that molybdenum molybdate  $\text{MoO}_3 \cdot 4\text{MoO}_3$  is soluble in alcohol, but not in ether. He also says that below certain concentrations, sulphuric and hydrochloric acids diminish the solubility of the blue double oxide in water without altering its composition. Diethyl ether did not extract the blue compound from the ore, nor from the blue water-soluble portion of the ore. However, when sulphuric or hydrochloric acid was added to the blue water solution, the solubility of the blue compound was diminished, and the blue color of the water layer was partially transferred to the ether layer on shaking. Under certain conditions to be described later, and by washing the ether extract with dilute hydrochloric acid, it is possible to completely remove the iron from the blue compound which remains dissolved in the ether. The ether may then be evaporated and the reduced as well as the total molybdenum determined.

The method used to determine the reduced molybdenum in the ether extract was to allow the ether to evaporate at room temperature until nearly all had evaporated. The remainder was then evaporated rapidly *in vacuo*, the process being continued for a time in order to remove all hydrochloric acid. The blue compound was then dissolved in water, filtered, and titrated with hundredth-normal permanganate, 5 cc. of 1:1 sulphuric acid being added to the blue water solution. The reduced molybdenum was calculated as  $\text{MoO}_3$ . A negative correction for a blank determination was applied to the titration in the following manner: Hydrochloric acid and ether of the same volumes as used in the extraction were shaken together, separated, the ether evaporated and titrated with permanganate. The total molybdenum in the same solution was determined by evaporating the solution to fumes with sulphuric acid, diluting with water, and then adding an excess of sodium hydroxide solution. The precipitate of manganese hydroxide is filtered off, and examined for traces of iron. It is not usually necessary to make a reprecipitation at this point. The filtrate is acidified with sulphuric acid, about 2½ per cent excess acid being added, and the molybdenum determined by passing the hot filtrate through the Jones reductor, according to the method of Randall.<sup>17</sup>

#### EXTRACTION OF THE BLUE COMPOUND WITH ETHER

Two hundred grams of ore was extracted successively with small portions of hot water until the volume of the filtrate was 500 cc. Most of the water-soluble blue material was removed by this treatment. An aliquot of 200 cc. was transferred to a separatory funnel, and 50 cc. of hydrochloric acid (conc.) added. The mixture was then cooled under the water tap, and 200 cc. of ether added. This was shaken vigorously, and cooled during the shaking. The layers of ether and water were then allowed to separate, and the water layer drawn off into another separatory funnel, and again extracted with 100 cc. of ether. After separation of the two layers, the ether extracts were combined, and washed ten times with 10 cc. of concentrated hydrochloric acid diluted to 25 cc. with water. Acid of this concentration dissolves but a very small portion of the blue compound originally extracted by the ether. The acid washings were tested for iron, and the process discontinued when

<sup>12</sup>Liebig's *Annalen*, 144, 227, 1867.

<sup>14</sup>Guichard, *Compt. Rend.*, 129, 722, 1899.

<sup>15</sup>Liebig's *Annalen*, 238, 114, 1857.

<sup>16</sup>Loc. cit.

<sup>17</sup>*Amer. Jour. Sci.*, 21, 313, 1907.

all was removed. After the washing was complete, the ether extract was allowed to stand for about two hours to complete the separation of suspended dilute acid. This was then drawn off, and the reduced and total molybdenum determined.

The extraction process as outlined does not remove all of the blue compound from the water solution. This may be accomplished by increasing the concentration of hydrochloric acid, and then extracting about three times more with 100 cc. portions of ether. However, if all the blue compound is extracted, it will be found impossible to wash all of the iron out of the ether extract, and ferric iron will be formed. The ferric iron will oxidize some of the reduced molybdenum, and the per cent of molybdenum in the reduced condition will be lowered.

It was found that when the blue material was totally extracted by ether from the water layer that all of the molybdenum was at the same time removed. This would indicate that the blue material is a compound, and, therefore, of definite composition. It at least possesses the property of being completely soluble in ether saturated with hydrochloric acid. All attempts to show definiteness of composition by extracting a given aliquot in two stages, and determining the per cent reduced molybdenum in each extract failed, because it was impossible to remove the iron from the second and complete extraction of the blue color from the water.

Numerous determinations showed that the blue material extracted by ether contained from 11.5 to 12.5 per cent reduced molybdenum, assuming the reduced molybdenum to be present as molybdenum dioxide ( $\text{MoO}_2$ ). This amount of reduced molybdenum accounts for 50 per cent of the water-soluble blue compound, which is extracted by ether if it be present in the heretofore accepted form of molybdenum molybdate ( $\text{MoO}_3 \cdot 4\text{MoO}_3$ ). The blue material extracted by ether, after removal of iron, does not give a test for sulphates. As about one-half of the blue compound, from a given volume of water extract, may be removed by ether, then at least one-half of the water-soluble molybdenum may be obtained free of sulphates. The only reason that all of the water-soluble molybdenum may not be obtained free of sulphates is because the ether extract cannot be washed free of iron sulphate if all of the "molybdenum blue" is removed from the aqueous layer.

#### DIRECT TITRATION

In view of the results just given, and their marked difference from those obtained by Schaller,<sup>18</sup> it was considered advisable to determine the amount of reduced molybdenum in the water-soluble portion of the ore by the direct titration of the water solution. Schaller found that direct titration of this solution with permanganate exactly equals the amount of iron (as ferrous iron) determined gravimetrically.

Determination of reduced molybdenum in the water solution by direct titration with permanganate, and then the determination of total iron and total molybdenum, and calculation of the amount of reduced molybdenum from the difference between the iron and the direct titrations involves the assumption of the absence of ferric iron. Tests for ferric iron on freshly prepared water extracts of the ore with molar am-

monium thiocyanate solution were negative. If one milligram of ferric iron in 1 cc. of water be added to 9 cc. of the blue solution, and a few drops of thiocyanate solution be added quickly, the characteristic red coloration is produced. As soon as the ferric iron solution is added to the blue solution, the blue color becomes less intense, due to the oxidation of the blue compound. However, the rapid addition of thiocyanate suffices to detect the presence of that portion of the original milligram of ferric iron remaining unreduced. If the thiocyanate is not added quickly, the iron added is reduced, and does not give the red coloration.

Tests on the water-soluble portion of the ore for sulphur dioxide and hydrogen sulphide were negative. As ferric iron is also absent, the direct titration method as outlined should give an accurate determination of the amount of reduced molybdenum.

By quickly preparing and titrating the water-soluble material from 200 grams of the ore in five equal aliquots with standardized permanganate solution, 12 per cent of the total molybdenum present was found to be in the reduced condition. This figure agrees very well with the amount of reduced molybdenum determined by the ether extraction method. The iron in the same aliquots was determined by reducing with zinc (reductor), and titrating with the same solution of permanganate. The total molybdenum was determined in the filtrate from the iron (two precipitations) by the method already given.

#### ANALYSIS OF WATER-SOLUBLE MATERIAL

A quantity of ore (250 grams) sufficient to approximately saturate 100 cc. of water was boiled with the water for about twenty minutes. This was then filtered, washed with 50 cc. of cold water, and evaporated to dryness. The dark blue solid was dried at 105 deg. C., and examined quantitatively for the ordinary radicals with the following results:

|                                      | Per Cent |
|--------------------------------------|----------|
| Silica, ( $\text{SiO}_2$ )           | 9.98     |
| Alumina, ( $\text{Al}_2\text{O}_3$ ) | 10.62    |
| Ferrous oxide, ( $\text{FeO}$ )      | 9.58     |
| Titania, ( $\text{TiO}_2$ )          | trace    |
| Calcium oxide, ( $\text{CaO}$ )      | 1.24     |
| Magnesium oxide, ( $\text{MgO}$ )    | 1.36     |
| Sulphur trioxide, ( $\text{SO}_3$ )  | 38.48    |
| Molybdic oxide, ( $\text{MoO}_3$ )   | 23.85    |
| Chlorine, ( $\text{Cl}$ )            | 0.17     |

This is not a complete analysis. The sample analyzed contained 1.10 per cent moisture, as determined by drying at 150 deg. C. for one hour. The loss on ignition was 43.8 per cent, but this represents a loss of molybdenum, and possibly water of hydration.

If all of the iron oxide, alumina, lime and magnesia are present as sulphates, one gram of the material would require 0.4010 grams of sulphur trioxide. One gram would contain only 0.3848 grams of sulphur trioxide. However, some silica and a small amount of chlorine are present. On this basis the 23.85 per cent molybdic oxide (total Mo calculated as  $\text{MoO}_3$ ) could not be in the form of a sulphate. Schaller proposed his sulphate formula for ilsemanite without determining alumina, lime and magnesia if present in the sample examined by him.

#### MISCELLANEOUS PROPERTIES OF THE BLUE SOLUTION

Qualitative ionic migration experiments on the water-soluble portion of the ore showed that the blue color behaved as a cation. With a current of 80 milliamperes,

<sup>18</sup>Loc. cit.

the movement toward the negative electrode is apparent after about 30 minutes. Other carriers, however, were present in the agar-agar blue layer besides the blue compound, as the blue water extract of the ore was used in making up the tube. With a small amount of hydrochloric acid present in the blue layer, a similar effect was noted. The results would seem to indicate that the cation of the blue compound is also blue, and that probably the  $\text{MoO}_2$  ion is acting as the positive carrier, though the effect may denote colloidal migration. Guichard<sup>28</sup> states that the molybdate of the dioxide of molybdenum ( $\text{MoO}_2 \cdot 4\text{MoO}_3 \cdot 6\text{H}_2\text{O}$ ) is a colloid. In this connection, it is interesting to note that the similar divalent compound of uranium, the uranyl radical ( $\text{UO}_2$ ) has decidedly basic properties, and that on electrolysis of its salts the uranyl ( $\text{UO}_2$ ) ion migrates to the cathode.<sup>29</sup> Among the members of Group VI of the periodic classification, which included molybdenum, the dioxides  $\text{R}^{\text{VI}}\text{O}_2$ , of the members of low atomic weights, sulphur, selenium and tellurium are acidic or neutral. As the atomic weight of the elements increase, the basicity of the radical  $\text{R}^{\text{VI}}\text{O}_2$  also increases, and the compounds formed become more stable. Brownish violet molybdenum dioxide ( $\text{MoO}_2$ ) united with white or yellow molybdic oxide ( $\text{MoO}_3$ ) to form blue molybdenum molybdate ( $\text{MoO}_2 \cdot 4\text{MoO}_3$ ); brown tungsten dioxide ( $\text{WO}_2$ ) interacts with yellow tungstic oxide ( $\text{WO}_3$ ) to form blue and purple-red tungsten tungstates; while brown uranium dioxide ( $\text{UO}_2$ ) and brownish-red uranic oxide ( $\text{UO}_3$ ) form green and black uranium uranates.

Guichard<sup>28</sup> prepared molybdenum dioxide by electrolysis of molten molybdic oxide, and Junius<sup>30</sup> has obtained blue molybdenum molybdate of the formula  $\text{Mo}_2\text{O}_7$ , at the cathode by the electrolysis of molybdic oxide in strong hydrochloric acid.

One-half gram of ammonium molybdate was evaporated nearly to dryness with sulphuric acid. After standing some time, the characteristic molybdenum blue color developed. Extraction of the blue color with ether in the presence of hydrochloric acid showed that only 8 per cent of the molybdenum had been converted into the blue compound. The remaining molybdenum sulphate was not nearly so soluble in ether as the blue of ilsemanite. If the blue of ilsemanite is molybdenum sulphate, then it should not be entirely soluble in ether saturated with hydrochloric acid. However, as pointed out under the section "Extraction of the Blue Compound with Ether," it is entirely extracted by ether.

The blue water extract makes an excellent ink, though it is slowly oxidized in the air. The blue color of the writing is discharged by hydrogen peroxide, but reappears if moistened with stannous chloride solution. Sulphur dioxide does not produce analogous results.

#### CONCLUSIONS

The above work does not constitute a basis for the proposal of a formula for ilsemanite. The formula proposed by Schaller<sup>23</sup> ( $\text{MoO}_3 \cdot \text{SO}_3 \cdot 3\text{H}_2\text{O}$ ) is not supported by the present investigation. Muthmann's<sup>24</sup> formula ( $\text{MoO}_2 \cdot 2\text{MoO}_3$ ) more nearly fits the properties of the

compound as determined, but requires perhaps too much reduced molybdenum. Guichard<sup>28</sup> has shown the formula of Muthmann for the synthetic blue oxide ( $\text{MoO}_2 \cdot 2\text{MoO}_3 \cdot x\text{H}_2\text{O}$ ) to be inaccurate; that it really is  $\text{MoO}_2 \cdot 4\text{MoO}_3 \cdot 6\text{H}_2\text{O}$ . But even Guichard's formula does not fit the blue of ilsemanite completely; as the water-soluble portion of the molybdenum in the ore does not contain sufficient reduced molybdenum. However, it is preferable for the present to consider the ore examined as a mixture containing the original parent molybdenum mineral, and water-soluble ilsemanite of Guichard's formula together with other water-soluble oxides of molybdenum formed in the alteration process.

#### EXTRACTION OF MOLYBDENUM FROM THE ORE

The methods employed in treating the ore are divided into four general classes: Extraction with water, extraction with dilute acids, with dilute alkali carbonates and alkalies, and by roasting with a small amount of various reagents followed by a water leach. Obviously fusion methods, such as are being used on wulfenite concentrates, would not be commercially applicable to a one per cent molybdenum ore.

It is not intended to convey the impression that all or any of the methods given could be used profitably in extracting molybdenum from the ore. A problem of this nature, of necessity, depends on many conditions outside of the laboratory. It is hoped that suggestions given here may be of some use if other conditions warrant the development of this deposit of ilsemanite.

Unless otherwise noted, the ore used in the following experiments was of the following size: Thirty-five per cent is retained on 40 mesh screen; 35 per cent passes 40 mesh, but is retained on 80 mesh, and 30 per cent passes 80 mesh.

#### LEACHING EXPERIMENTS WITH WATER AND ACIDS

The plan followed in determining the per cent of molybdenum that could be extracted by water was as follows: A sample of the ore (10 grams or more) was treated with successive portions of water, until the filtrate from the water leach showed little or no blue color. The water solution was then oxidized with nitric acid, the blue color disappearing, taken to fumes with sulphuric acid, diluted, and made alkaline with sodium hydroxide. The precipitate was filtered off, the filtrate made acid with sulphuric acid, heated to about 70 deg. C., and passed through the Jones reductor into a solution of ferric ammonium sulphate decolorized with a few cc. of syrupy phosphoric acid. This was then titrated with standard potassium permanganate to a one-half-minute pink. In order to determine the solubility of the ore in a large excess of water, one gram was leached with 150 cc. of hot water. The residue was dried at 105 deg. C.; 4.34 per cent of the ore was found to be soluble. The residue contained a little less than 15 per cent molybdic oxide.

If 10 grams of ore is treated with three successive portions of hot water of 30 cc. each, coming to a boil each time, between 46 and 54 per cent of the molybdenum in the ore is removed. These results have been confirmed by numerous trials.

In order to determine the quantity of ore required to give the highest concentration of molybdenum in a given

<sup>28</sup>Loc. cit.

<sup>30</sup>Am. Chim. Phys. series 7, 23, 563, 1901.

<sup>31</sup>Zeit. Anorg. Chem., 46, 428, 1905.

<sup>32</sup>Loc. cit.

<sup>33</sup>Loc. cit.

<sup>34</sup>Loc. cit.

volume of water, separate portions of 5, 10, 15, 20 and 25 grams of the coarser mesh ore were treated with 10 cc. of water each. The water was allowed to come to the boiling point, when the entire contents of each beaker were placed on separate filters. The residues on the paper were then washed with 10 cc. of cold water, and the molybdenum content of the filtrates determined. The results are given below:

|                                            |     |     |     |     |     |
|--------------------------------------------|-----|-----|-----|-----|-----|
| Grams of ore.....                          | 5   | 10  | 15  | 20  | 25  |
| Cubic centimeters of $\text{KMnO}_4$ ..... | .17 | .27 | .34 | .36 | .38 |
| Per cent Mo extracted.....                 | .46 | .40 | .33 | .28 | .23 |

These results show that saturation has not been quite reached, but that approximately one part of water requires from two and one-half to three parts of the ore. The cc. of  $\text{KMnO}_4$  used in the data tabulated above refers to molybdenum present in the water-solution. One cc.  $\text{KMnO}_4$  is equivalent to 0.00132 grams Mo; per cent Mo extracted means the per cent of the total present extracted.

#### EXTRACTION OF THE ORE WITH COLD WATER

Twenty-five grams of the ore, and 10 cc. of water at room temperature were allowed to stand for one hour. The solution was then filtered off, and the Mo in the filtrate determined. The residue was leached one hour with another 10-cc. portion of cold water, filtered, and the Mo determined. This operation was repeated four times in all. The result are as follows:

| Extraction No.             | 1   | 2   | 3  | 4  | Total per cent of Mo extracted |
|----------------------------|-----|-----|----|----|--------------------------------|
| Per cent Mo extracted..... | .12 | .15 | .3 | .4 | 2.5 33.5                       |

To determine whether a finer mesh would permit the extraction of a larger per cent of the molybdenum, a portion of the sample above mentioned was ground to pass 150 mesh. This was then extracted with hot water along with a sample of the coarser material. After three hot water leaches of 30 cc. each, the residues were extracted with 50 cc. of hot 15 per cent sulphuric acid. The results are given below:

|                                                                  | Coarse mesh | 150 mesh |
|------------------------------------------------------------------|-------------|----------|
| Per cent extraction Mo hot water.....                            | 54          | 57       |
| Additional per cent extraction Mo in hot 15% sulphuric acid..... | 16          | 27       |
| Total extraction water and acid.....                             | 70          | 84       |

It will be noted that fineness of the ore does not materially increase the percentage extraction in the case of water, but that it does increase it if the water leach is followed by sulphuric acid. Perhaps with additional acid leaches all of the molybdenum might be extracted. Ten grams of ore leached successively with three 30 cc. portions of hot water followed by 50 cc. of 1:1 ammonium hydroxide gave an extraction of 63 per cent; while the same weight of ore leached with two 50 cc. portions of 1:1 ammonium hydroxide gave only a 39 per cent extraction.

#### COMPARATIVE RESULTS ON LEACHING WITH WATER AND ACIDS

Additional leaching experiments with water and acids on both the coarse-mesh ore and the 150-mesh ore gave results as indicated in Table I; in each case 10 grams of ilsemaninite and boiling reagents were used.

The best results are given by 5 per cent sulphuric acid. It will be observed that the finer mesh ore gives much better yields with all acids; also that in most instances a preliminary treatment with water followed by acid gives a somewhat better yield than the reverse

TABLE I—LEACHING EXPERIMENTS

| Treatment of Ore                                                                                                                                                    | Per Cent Mo Extracted |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| No. 1. Coarse mesh ore leached with two 30-cc. portions of boiling water, followed by 50 cc. of 5% boiling $\text{H}_2\text{SO}_4$ , then 10 cc. of cold water..... | 67                    |

| No. 5. Coarse ore, two 30 cc. water, then 20 cc. 15% $\text{H}_2\text{SO}_4$ , 10 cc. cold water.....                                                               | 64                    |
| No. 6. 150-mesh ore, treated as No. 5.....                                                                                                                          | 79                    |
| No. 7. Coarse ore, 20 cc. 15% $\text{H}_2\text{SO}_4$ , then two 30 cc. water followed by 10 cc. cold water.....                                                    | 62                    |
| No. 8. 150-mesh ore, same as No. 7.....                                                                                                                             | 76                    |
| No. 9. Coarse ore, two 20 cc. water, 20 cc. 5% $\text{HCl}$ , 10 cc. cold water.....                                                                                | 64                    |
| No. 10. 150-mesh ore, same as No. 9.....                                                                                                                            | 80                    |
| No. 11. Coarse ore, 20 cc. 5% $\text{HCl}$ , two 20 cc. water, then 10 cc. cold water.....                                                                          | 61                    |
| No. 12. 150-mesh, same as No. 11.....                                                                                                                               | 83                    |
| No. 13. Coarse ore, two 20 cc. water, 20 cc. 2% $\text{HNO}_3$ , 10 cc. cold water.....                                                                             | 70                    |
| No. 14. 150-mesh ore, same as No. 13.....                                                                                                                           | 79                    |
| No. 15. Coarse ore, 20 cc. 2% $\text{HNO}_3$ , two 30 cc. water, 10 cc. cold water.....                                                                             | 70                    |
| No. 16. 150-mesh, same as No. 15.....                                                                                                                               | 77                    |

treatment. It is improbable, however, that a process involving the use of 150-mesh ore could be used commercially. It was also determined that reduction of the sulphuric acid concentration much below 5 per cent gives such a poor extraction as to render it useless.

#### LEACHING EXPERIMENT WITH AQUEOUS CAUSTIC SODA AND SODIUM CARBONATE

Ten grams of the ore with 0.25 grams of sodium carbonate and 50 cc. of water were heated to boiling, and the soluble material then filtered off. The residue in the beaker was washed by decantation with two 25-cc. portions of boiling water. The molybdenum in the aqueous extract was then determined, and the per cent of the total present that had been removed computed. This experiment was then repeated, using sodium hydroxide instead of sodium carbonate, exactly the same amount as those given above being used.

| Per cent Mo Extracted..... | $\text{Na}_2\text{CO}_3$<br>60 to 66 | $\text{NaOH}$<br>78 to 82 |
|----------------------------|--------------------------------------|---------------------------|
|----------------------------|--------------------------------------|---------------------------|

The color of the sodium carbonate extract was blue, but that of the sodium hydroxide extract was brown to yellow, filtering with more difficulty than the carbonate. The ratio of the weight of reagent to that of the ore is equivalent to 50 pounds of reagent per ten of ore. Using 25 pounds of sodium hydroxide per ton of ore in exactly the same manner as the above, an extraction of 67 per cent was obtained.

An experiment on a larger scale using 50 pounds of minus 30-mesh ore and 1.25 pounds of sodium hydroxide in 200 pounds of water gave an extraction of 72 per cent of the molybdenum, calculated on the basis of the heads and tails.

In addition to the wet methods used above, the ore was roasted with various reagents at a temperature below 600 deg. C. Sodium chloride, sodium nitrate, sodium pyrosulphate and charcoal were tried alone, and in mixtures of one part of reagent or mixtures of reagents to ten parts of ore. The sintered cake resulting was then extracted with hot water. In no case was the extraction improved over that of hot water alone. The extraction of molybdenum varied from 16 to 28 per cent.

I desire to express my thanks to Dr. R. B. Moore, under whose direction the above work was carried out, and to Dr. S. C. Lind for a number of helpful suggestions.

Golden, Colorado.

# The Metallography and Heat Treatment of Metals Used in Aëroplane Construction—II

## Investigation of Parts Made From Medium-Carbon, High-Carbon and Chrome-Nickel Steels—Causes of Failure in Cam Wheels, Piston Pins and Crank Shafts

By F. GROTT'S  
Chief Metallurgist, Curtiss Aëroplane and Motor Corporation

### MEDIUM-CARBON STEEL

THIS steel is called forging stock and from it are made propeller hubs, wing plates, strut sockets, hinges, both male and female, bolts, etc. Average chemical analysis: Carbon 0.35, manganese 0.65, sulphur 0.04, and phosphorus 0.032 per cent.

The raw stock has the following physical properties:

|                        |        |
|------------------------|--------|
| Ultimate strength, lb. | 80,800 |
| Yield point, lb.       | 54,600 |
| Elongation, per cent.  | 33     |
| Reduction, per cent.   | 62     |
| Brinell                | 153    |
| Scleroscope            | 30     |

Heat treatment of 1550 deg. quenched in oil and drawing at 965 deg.

|                        |        |
|------------------------|--------|
| Ultimate strength, lb. | 96,000 |
| Yield point, lb.       | 68,090 |
| Elongation, per cent.  | 29     |
| Reduction, per cent.   | 68     |
| Brinell                | 194    |
| Scleroscope            | 36     |

The principal defects found in this type of steel are pipes and slag inclusions. The pipe shown in Fig. 32 was heated at a temperature of 1600 deg. for one hour and a half in an attempt to improve it. There was no marked change. Material of this type will grow worse or the pipe will grow on usage. This illustration is of interest because it is thought by some that heat treatment will do away with pipes.

This material has given less trouble than any other as it responds very nicely to heat treatment, i.e., gives the necessary physical properties, and there have been few rejections from slag, pipes, excess phosphorus or sulphur.

On several occasions this stock has been mixed with nickel steel. The separation was brought about by taking a small section from each rod and quenching all at a temperature of 1500 deg. and scleroscoping. The nickel scleroscoped about 60, and the carbon steel 40.

One or two illustrations were found of a brittleness that was probably caused by the pickling operation. The reaction of the acid on the steel gave off hydrogen which was absorbed and gave rise to the defect. Concentrated caustic solutions at a boiling temperature used for removing the quenching oils also gave a slight attack, as in the case of the pickling.

Some tests have shown a variance in crystal size. This depends on many factors, principal of which are the temperature of the steel prior to rolling, the deformation during rolling, the finishing temperature, and the rate of cooling.

Owing to the many variables it is difficult to arrive at any accurate method of calculating the strength of a steel of this type from the chemical analysis. The following data give a fairly good approximation.

**Carbon**—In acid steel each 0.01 per cent carbon strengthens the steel by 1000 lb. per square inch. In basic steel each 0.01 per cent strengthens the steel by about 700 lb. per square inch.

**Phosphorus**—Each 0.01 per cent strengthens the steel by about 1000 lb. per square inch.

**Manganese**—In acid steel each 0.01 per cent above 0.4, about 200 lb. per square inch. *Basic steel*, about 90 lb. per square inch.

The strength derived from manganese increases as the carbon content decreases.

PLATE 2.—PROPERTIES OF MEDIUM CARBON STEEL

**Sulphur**—Practically has no strengthening effect. Formula—Acid Steel:

$$40,000 + 1000C + 1000P + 200Mn = \text{Raw stock.}$$

Basic Steel:

$$42,000 + 700C + 1000P + 90Mn = \text{Raw stock.}$$

Raw stock + 33 per cent = Quenched stock.

Quenched stock—2000 lb. for each 100 deg. draw.

A cam wheel on showing peculiar properties (softness, distortion) after being used was investigated to

FIGS. 26-36

Figs. 26-31—Medium Carbon Steel, Analysis: C, 0.35 per cent; Mn, 0.65; P, 0.01; S, 0.032. Etched with picric acid; x 100. Fig. 26—annealed; 27—quenched; 28—quenched and drawn at 800 deg.; 29—quenched and drawn at 1000 deg.; 30—quenched and drawn at 1200 deg.; 31—raw stock. Fig. 32—Pipe in medium carbon steel. Fig. 33—Section taken through cam on wheel. Fig. 34—Section of wheel some distance from cam, showing general structure. Fig. 35—Control lever before quenching and drawing. Etched with picric acid; x 100. Fig. 36—Control lever properly treated.

determine the cause of said properties. This material was supposed to be medium carbon steel cyanided at 1600 degrees for ten minutes and quenched in water.

The wheel was first scleroscoped carefully, then sections were taken and quenched and again scleroscoped. Near the cam a section was taken; then one some distance away. These were polished, etched with picric acid and photographed at a magnification of 100. The photomicrographs are shown in Figs. 33 and 34. The scleroscope test of the wheel, as received, gave 27; after quenching in water at 1475 deg., 29; quenching at 1550 deg., 31. A chemical analysis gave the following results: C, 0.09 per cent; Mn, 0.37; S, 0.101; P, 0.112; Fe, 98.

*Summary*—The material is very poor and has been slightly case-hardened on the bearing or concave surface.

Fig. 34 shows that it is very low carbon stock with a very poor structure as one would expect from screw stock (high S and P).

Fig. 33 taken from the cam shows where the material is distorted by usage; also slightly carbonized. It would be impossible to handle such material in any way to get satisfactory results.

An excellent material for this part is chrome-nickel steel. By heat-treating it will give all of the necessary properties and will be superior to any carbon steel.

CONTROL LEVER INVESTIGATION

This lever on being placed in the machine bent and was too soft for service. It was supposed to have been made of medium carbon steel (0.32 per cent) and quenched at 1550 deg. in oil and drawn at 1000 deg.

The object of the investigation was to determine if possible the explanation of the objectionable properties. A chemical analysis showed C, 0.31 per cent; Mn, 0.55; S, 0.046 and P, 0.023.

Scleroscope 28 and Brinell 145.

A section was taken, polished, etched with picric acid and photographed at a magnification of 100. This section was then taken, quenched at 1550 deg. and drawn at 1000 deg. This was also photographed.

Fig. 35 shows the lever as it was and Fig. 36 shows it properly treated.

*Summary*—The lever had been annealed (Fig. 35) and left in that condition. A proper heat treatment of about 1550 deg. quench in oil and draw at 1000 deg. would have shown a scleroscope hardness of 35 to 40 and a Brinell of 195 to 210. Fig. 36 shows the structure of the material properly handled.

It is well at this point to take into consideration the use of the scleroscope. This is a very valuable piece of apparatus in connection with heat-treating. It is recommended that the material be scleroscoped before and after heat treating.

*Precautions in using:*

- 1. Instrument should be mounted on a firm base in good light.
- 2. A good smooth surface with a fine file are necessary.
- 3. Round specimens should be tested on the end and not the curved surface.
- 4. Take the mean of several readings.
- 5. Do not take two readings in the same place—shift the apparatus.

HIGH-CARBON STEEL

Tail-skid shoes, cable wire, and some springs are made from high-carbon steel. There is considerable trouble in heat-treating this steel as it will crack when quenched cold. It is preferable to heat to the quenching temperature (1450 deg.) and after quenching remove from the oil before cold or while it has a temperature of probably 200 deg. This will give a slight draw-back and will relieve any strains. Hot water has been used with good results on this material. Oil gives a better and tougher result than can be obtained from any other quenching medium.

The chemical analysis of this stock is 0.93 per cent C, 0.35 Mn, 0.016 S, and 0.035 P. By lowering the

PLATE 3.—PROPERTIES OF HIGH CARBON STEEL

carbon to about 0.55 and increasing the manganese to 0.85 there will result as good a material if not better for shock-resisting properties.

Raw stock physical properties:

|                        |         |
|------------------------|---------|
| Ultimate strength, lb. | 113,000 |
| Yield, lb.             | 72,200  |
| Reduction, per cent.   | 38      |
| Elongation, per cent.  | 20      |
| Brinell                | 223     |
| Scleroscope            | 38      |

Quenched at 1450 deg. in oil and drawn at 650 deg.:

|                        |         |
|------------------------|---------|
| Ultimate strength, lb. | 184,000 |
| Yield, lb.             | 132,000 |
| Reduction, per cent.   | 33      |
| Elongation, per cent.  | 11      |
| Brinell                | 385     |
| Scleroscope            | 60      |

Cable wire has a high tensile strength. In some instances it is too hard to comply with the bend tests in which case it is slightly drawn at from 450 to 600 deg. Much of this material has been rejected because of fine cracks which were probably caused from trying to obtain a too high tensile strength by straining in cold drawing.

FIGS. 37-48

Figs. 37-40—High Carbon Steel. Analysis: C, 0.93 per cent; Mn, 0.35; S, 0.016; P, 0.025. Etched with picric acid; x 100. Fig. 37—quenched; 38—quenched and drawn at 800 deg.; 39—quenched and drawn at 1000 deg.; 40—quenched and drawn at 1200 deg. Figs. 41-44—Chrome Nickel Steel. Analysis: C, 0.30 per cent; Si, 0.19; Mn, 0.51; S, 0.029; P, 0.042; Cr, 0.61; Ni, 1.79. Etched with picric acid; x 100. Fig. 41—raw stock; 42—quenched; 43—quenched and drawn at 1000 deg.; 44—quenched and drawn at 1200 deg. Fig. 45—Hardening cracks in piston pin. Etched with picric acid; x 100. Fig. 46—Sorbite structure of piston pin drawn at 350 deg. Fig. 47—Inclusion showing as hair line in surface of crank shaft. Fig. 48—Inclusion in same shaft some distance from Fig. 47.

High tension or aviation wire and cable of an average analysis of 0.75 per cent C, 0.60 Mn, 0.032 P and 0.027 S, has a tensile strength of about 250,000 lb. per sq.in. The ends of these wires and cables are made into loops and soldered.

When soldering the loops on the ends of wire and cable, due care should be exercised not to draw or anneal the steel. It is good practice to have some kind of a temperature control on the soldering baths, if used instead of irons or in connection with irons. Acid fluxes cause corrosion especially when the cables are on sea planes and salt water comes in contact with the part already affected. Where acid attacks the surface of the steel, the weakened area formed by the corrosion acts like a file cut, and vibration soon causes the rest, resulting ultimately in rupture under strain.

CHROME-NICKEL STEEL

Chrome-nickel steel is made into piston pins, connecting rods and crank shafts, steam-line wire, etc.

PLATE 4.—PROPERTIES OF CHROME NICKEL STEEL

It is good to resist shock and has a high tensile strength. The presence of both chromium and nickel produces a steel that has a high elastic limit combined with increased elongation and reduction, greater hardening power, and wears much better than carbon steels. This steel is especially valuable in parts that necessitate a heat treatment as it yields a fine martensitic structure superior to carbon steels. It resembles the 3 1/4 per cent nickel steel when carbonized in that it may be quenched at about 1550 deg. and refine both the case and core at the same operation.

A typical chemical analysis of this type of steel is C 0.30 per cent, Si 0.19, Mn 0.51, S 0.029, P 0.042, Ni 1.79, and Cr. 0.61.

Raw stock physical properties:

|                       |         |
|-----------------------|---------|
| Ultimate tensile, lb. | 122,000 |
| Yield, lb.            | 108,800 |
| Reduction, per cent.  | 55.8    |
| Elongation, per cent. | 13.0    |
| Brinell               | 255     |
| Scleroscope           | 40      |

Quenched at 1550 deg. and drawn at 900 deg.:

|                       |         |
|-----------------------|---------|
| Ultimate tensile, lb. | 180,000 |
| Yield, lb.            | 150,000 |
| Reduction, per cent.  | 40      |
| Elongation, per cent. | 13      |
| Brinell               | 360     |
| Scleroscope           | 56      |

There has been some trouble in heat-treating this material, piston pins especially often showing hardening cracks. It is sometimes a good plan to double-quench this material before drawing, at 1575 deg. then at 1500 deg. in oil or hot water, being careful to quench the pins vertically. This seems to give a much better result.

The following is a typical illustration of poor heat-treating of this kind of steel. A piston pin broke after a ten-hour run in a motor. The section showed a hardness of 79, and on being drawn at 850 deg. for thirty minutes scleroscoped 55. The photomicrographs (Figs. 45 and 46) show that the pin was too hard and that it was full of hardening cracks, eight being found. The section that was drawn showed a sorbitic structure in which the ferrite has followed the original martensitic needle lines.

**Summary**—The chemical analysis of this pin was C 0.38 per cent, Mn 0.51, S 0.026, P 0.018, Ni 3.24, and Cr. 1.25. This is very good, and where there are no bad inclusions or seams, pins should not crack when quenched and drawn as before suggested. The pins investigated were probably quenched cold which set up internal strains that yielded the hair cracks. It was apparently not drawn.

Crank shafts made of chrome-nickel steel often contain hair lines or inclusions of manganese sulphide and silicate. They are objectionable due to the fact that they form surface cracks that will have a destroying effect on soft metal bearings; also they form slight lines of weakness. Cranks of this type will often give satisfactory results, but where the inclusions are of the size shown in Figs. 47 and 48 they should be regarded with suspicion, especially so when found in the "cheeks" of the shaft.

In considering the acceptance or rejection of such a shaft the location, size and type of inclusion should be taken into consideration. The inclusion shown in Fig. 48 was about 0.022 in. in depth and in case of its occurrence in a part of the shaft subject to torsion there is no question but that there is danger of failure, especially when there is poor alignment of bearings. These defects result from poor metallurgy, but by the proper proportioning of Al, Si, and Mn, could be done away with. This would increase the piping but this defect could be removed in the discard. The so-called snow flake does not occur in shafts of this analysis. The particular shaft that showed these hair lines had a composition of C 0.33 per cent, Mn 0.64, P 0.026, S 0.038, Cr 0.78, Ni 1.32 and had the following physical properties:

|                        |         |
|------------------------|---------|
| Ultimate strength, lb. | 150,000 |
| Yield point, lb.       | 120,000 |
| Elongation, per cent.  | 18      |
| Reduction, per cent.   | 56      |

FIGS. 49-56

Figs. 49 and 50—Mixed structure in crank shaft resulting from poor heat treatment. Photos taken at some distance from each other. Fig. 51—Same section as Fig. 49 given proper heat treatment. Figs. 52 and 53—Hair-line cracks in crank shaft due to improper quenching. Fig. 54—Pipe in gas pocket in crank shaft. Fig. 55—Torsional cracks in crank shaft. Fig. 56—Snow flake, due to forging at too low temperature.

Another shaft investigated failed in service. Sections taken from it had a chemical analysis of C 0.39 per cent, Mn 0.78, S 0.034, P 0.012, Ni 1.42, and Cr 0.82, and physical properties as follows:

|                           |         |
|---------------------------|---------|
| Ultimate tensile, lb..... | 142,000 |
| Yield point, lb.....      | 125,000 |
| Elongation, per cent..... | 18.7    |
| Reduction, per cent.....  | 55.4    |
| Brinell.....              | 256     |
| Scleroscope.....          | 48      |

From one end of this shaft to the other there was a variance of 42 to 52 on the scleroscope and 241 to 256 on the Brinell. The photomicrographs showed a mixed structure which probably resulted from poor heat treatment.

Figs. 49 and 50 were taken from the shaft at some distance apart, etched with nitric acid and photographed at a magnification of 100.

Fig. 51 shows the section illustrated in Fig. 49 after having been given proper treatment—a very fine sorbite. Quenched at 1600 and 1500 deg. in oil and drawn at 900 deg.

The shaft failed because of poor heat-treatment varying the physical properties of the shaft. It might also have been assisted by the bearings not being true. This has been found true in other cases of failure.

Some shafts are spoiled by quenching improperly. This gives rise to hair-line cracks. Hair-line cracks must not be confused with hair-line inclusions. The quenching medium should not be too rigid or abrupt, as cold water. Figs. 52 and 53 show hair-line cracks. They were about one-fourth of an inch deep and are sufficient cause for rejection. Shafts should be quenched in oil or warm water.

The faults in the shaft shown in Fig. 54 are due to a poor billet. They are pipes or gas pockets and probably could have been avoided by a larger discard. The serrated lines here shown in Fig. 55 are probably torsional cracks. This is a very serious defect, much more so than inclusions.

Snow flake as shown in Fig. 56 is a fault arising probably from forging at too low a temperature. It is a condition peculiar to steel of a higher nickel content.

#### CRANK SHAFT SUMMARY

The inclusions shown are of manganese sulphide and silicate. Sulphur prints show considerable discoloration from these areas.

Some shafts have stood up very well after a 100-hour run, while others show that cracks have begun to grow from the inclusions and still others have failed entirely, the failure being traced to the inclusion. As these inclusions can be avoided, and since they are unquestionably lines of weakness and do cause failures, why argue over their acceptance?

Hair cracks are sometimes traced from quenching in cold water. Sometimes they are started by improper

forging (forging strain). The cracks shown between the gas pockets in Fig. 54 would appear as hair cracks. Heat-treatment when not conducted properly will give a bad shaft. Variance of temperature in the furnace and crude quenching methods are the principal factors. Some pyrometers are found to be incorrect as much as 200 to 300 deg. F. Too much attention cannot be paid to the proper treatment of crank shafts. The gas pockets shown may be secondary pipes and the cracks connecting the pockets may be pipe-cracks (expansion and contraction). A pipe generally can be removed by properly discarding the top section of the ingot, by bottom pouring, or by the use of molds having a greater top diameter than bottom. In the case of green steel there are local gas pockets and this illustration may be one.

Snow flakes occur in this steel because of poor mill practice. The manufacturer in trying to rush the heat sometimes pours while green. This will sometimes give a condition as here shown. Furthermore, if a high-nickel bar of this steel be forged at too low a temperature there might be a condition such as this. I prefer to think that the fault herein shown traces its origin to poor mill practice.

(To be continued)

The First Veritable Platinum Ingot was made by a French chemist, Chabaneau, in 1783. Charles III of Spain had called him to Madrid and created a special chair of mineralogy, physics, and chemistry for him. Here in his laboratory he found the secret for rendering the new metal malleable, and astonished the court by the weight and lustre of his first ingot.

## Developments in Industrial Research\*

By CHARLES L. REESE

Chemical Director, E. I. duPont de Nemours & Co.

THE duPont Company started its research department June 1, 1902, by establishing what is known as the "Eastern Laboratory," at Gibbstown, N. J. A force of five chemists, including the Director, constituted its personnel. The Director's duties were two-fold: First, directing laboratory research work, and second, studying chemical operations of the high explosives plants.

In 1903, a second experimental laboratory, known as the "Experimental Station," was established in Wilmington to handle work specifically for the development department of the company. This was later extended to include also work in connection with the manufacture of black and smokeless powder.

In 1912, the "Delta Laboratory" was established for the purpose of investigating problems in connection with the manufacture of pyralin or celluloid, and in 1917 the "Jackson Laboratory" was established in connection with

PLAN OF RESEARCH ORGANIZATION

the dyes industry. All these experimental laboratories were placed either at, or in close proximity to manufacturing plants, in order to facilitate the study of plant problems.

Very soon after the establishment of the Eastern Laboratory, it was found desirable to have a head of the research department at the main office in Wilmington, Del., where the duPont Company's executive work is centralized, in order to provide a clearing house for the several research laboratories, and to have available a force of expert chemists who could not only keep in touch with actual manufacturing operations at the various plants, but who could act in a consulting capacity to the various departments. At the same time it was found advisable to centralize all chemical research work under one Chemical Director, and accordingly the Experimental Station, which had been connected with the development department, became a part of the chemical department organization.

\*Delivered at the meeting of the American Society for Testing Materials, Atlantic City, June 26, 1918.

The growth of the research activities since the establishment of the Eastern Laboratory in 1902 is well shown by the following tabulation, which gives the number of salaried employees, and the salaries paid per month during the last ten years:

|                    | 1908     | 1909   | 1910   | 1911   | 1912   | 1913   | 1914   | 1915   | 1916   | 1917   | June, 1918 |
|--------------------|----------|--------|--------|--------|--------|--------|--------|--------|--------|--------|------------|
| Employees..        | 55       | 75     | 92     | 111    | 111    | 115    | 95     | 160    | 200    | 395    | 475        |
| Salary per month.. | \$ 8,000 | 10,000 | 12,000 | 13,000 | 14,000 | 14,500 | 13,000 | 20,000 | 26,000 | 55,000 | 92,000     |

Not only has the number of salaried employees increased considerably during these ten years, but the salary rates have very decidedly increased, although this is not true of the average salary per man, due to the increased proportion of younger men employed during the last few years. Furthermore, as indicated by the accompanying curve, the total yearly expenditures for research work have grown from fifty thousand to two million dollars. This growth in research activity shows clearly that the duPont Company considers its research department a distinctly profitable undertaking.

During the period from 1912 to 1915, the total expenditures for research work amounted to approximately one million two hundred thousand dollars; while the total savings, direct or indirect, accomplished by this expenditure were fourteen million dollars. It is, of course, difficult, in fact almost impossible, to calculate the exact pecuniary saving brought about by many lines of research, but the above figures, which represent only savings which could definitely be traced to research activities, give some idea of the magnitude of what can be accomplished.

The diagram shows graphically the present organization of the chemical department of the duPont Company. In addition to the chemical force, which is directly engaged in research work, and which is represented by the chemical department with its several branches, the company employs a large number of graduate chemists in its various plants, either in plant laboratory work, or in the supervision of its chemical manufacturing operations. The total number of chemists employed at present, including those in the research department, is approximately eleven hundred.

#### DIRECT AND INDIRECT FINANCIAL RETURNS

The first important problem undertaken by the research department, when established, was a study of a difficulty met with in works operations, in the separation of nitro-glycerine from waste nitrating acid. After a few months' study this problem was solved by the discovery of the presence of colloided silica in certain brands of glycerine, which colloided silica hindered the separation of the nitro-glycerine from the acid. It was found that by the addition of minute quantities of sodium fluoride, the separation could be reduced from a period of two hours to one of but a few minutes. By this reduction in the time of separation, an enormous saving in time and cost of manufacture was accomplished, and the research department received immediate recognition.

From the first beginning to the present time, progress in research has been like a triumphal procession. Investigations of existing manufacturing processes led to changes in the manufacture of nitro-glycerine, nitric acid, sulphuric acid, and ammonium nitrate, all of which are raw materials for the manufacture of dynamite, nitrocellulose and ether for smokeless powder manu-

facture, and acid and solvent recovery; they have enabled us to obtain practically theoretical chemical yields in the manufacture of these products; and by improvements in machinery, equipment, methods of handling and by substitution of mechanical processes for labor, they have accomplished savings of millions of pounds of raw materials and a corresponding monetary saving.

Without going into this matter in detail, I wish to mention several developments which have occurred since the beginning of the war, and which will contribute in no small measure to a final successful end of it.

In 1914, when the British embargo cut off the supply of German potash salts, the duPont Company was in a position to undertake the immediate production of potash salts from its nitrate deposits in Chile, as the research department had already discovered the presence of these salts in these deposits, and had worked up a satisfactory method for their extraction. This achievement not only assists in helping to meet the shortage of potash salts, but insures a supply for the manufacture of black ignition powder, which is absolutely necessary for igniting and firing charges of smokeless powder in our large guns.

A threatened shortage in the supply of sheet lead, and an actual shortage of lead burners and the necessity for a tremendous increase in the production of sulphuric acid for the manufacture of explosives made it imperative to find a substitute for lead in the construction of sulphuric acid plants. This problem was solved satisfactorily, and to-day millions of pounds of sulphuric acid are being manufactured in plants which have not a pound of lead in their construction.

The problems of the manufacture of diphenylamine, a necessary ingredient in smokeless powder which prevents its deterioration, and of the raw material, aniline, used in the manufacture of diphenylamine, were quickly and satisfactorily solved in American research laboratories; and this ingredient, which was obtainable in large quantities only from Germany, is now manufactured in this country, thousands of pounds per day.

While these developments and achievements illustrate what has been done in the way of supplying requirements, or furnishing substitutes for raw materials difficult or impossible to obtain, the accomplishments in the field of conservation of material have been as great, if not greater. Two might be mentioned here which, from the standpoint of magnitude, are well worth noting. In the manufacture of the type of powder employed by the United States Army, and now largely employed by the Allies in Europe, large quantities of alcohol and ether solvent are required. On account of the volatility of both of these substances, large losses take place during the manufacture of powder. By studying carefully these losses in the places where they occur, changes in manufacturing operations were made possible which enabled us to save solvent which, under the present scale of manufacturing powder, would amount to some fifty million pounds per year. Likewise, in the manufacture of gun cotton, where large quantities of nitric acid were lost several years ago, we have been enabled by careful study to make changes which have accomplished a saving equivalent to some forty-five million pounds of nitric acid a year. When it is remembered that heretofore nitric acid has been manufactured almost entirely from

Chile saltpetre, and that the scarcity of shipping has made it difficult to maintain an adequate supply of this material, which is so essential for the successful raising of large crops, it will be realized what the chemical research of this one company alone has been able to contribute to the successful termination of the war, aside, and in addition to, the production of actual military explosives.

Before the United States entered the war, the demand for toluol became so great, and the price so high, that two distinct methods for the synthetic manufacture of this material were developed. Two methods for the manufacture of picric acid were also developed and operated satisfactorily.

There is a high explosive used for primers in military explosives, as well as in blasting caps, known as tetryl, or tetranitromethylaniline. A process for the manufacture of tetryl or tetranitromethylaniline was developed and put in satisfactory operation, as well as the process for manufacturing dimethylaniline.

Because of the extensive program for the manufacture of high explosives planned after the United States entered the war, it became necessary to develop other high explosives than trinitrotoluol, picric acid and ammonium nitrate, and within a very short period the research department developed four new high explosive materials, all of which have been adopted by the Government, and will materially relieve the situation.

It is hardly necessary to call attention to the developments carried on by the research laboratories, of not only the duPont Company, but also of a great number of other concerns which have resulted in a very satisfactory solution of the dye situation in this country, so that in a short time we will be producing all the important dyes which we were of necessity importing from Germany before the war.

These instances from the experience of one company could be multiplied many times and the list of accomplishments of every large industrial corporation maintaining an adequate staff of research chemists could be greatly extended. As it is, I have only indicated the general trend toward an increased amount of research work as evidenced by the expansion which has taken place in the duPont Company, suggesting the possibilities in saving, in conservation of resources, and in increasing efficiency which can be accomplished by such a systematized and well organized research work.

The President has issued an executive order authorizing the Secretary of War to employ, without reference to the requirements of the civil service act, such persons in the research division, Chemical Warfare Service, at the American University, as may be needed in conducting certain investigations and construction work relating to gases and chemicals used in war, it being understood that all possible use will be made of the registers of eligibles of the Civil Service Commission. This authority shall continue only during the present war. The Commission concurs with the War Department in recommending this order because of the urgent and highly confidential character of the work involved and the fact that it must be organized and prosecuted with the greatest dispatch and be safeguarded most effectively.

## "Caliche" Beds Found to Be Small in Southeastern California

REPORTS were circulated in 1917 that large deposits of sodium nitrate were in Amargosa Valley, Ingo County, California. The Geological Survey has made an extensive search without finding verifications. In all, 78 trenches were dug, which had a total length of 3700 feet and an average depth of 2 feet 11 inches; 959 pits were dug to an average depth of 1 foot 7 inches; 1035 samples were taken, from which 930 analyses were made. In the so-called Upper Canyon field, at Acme Siding, 98 acres is estimated to contain 1430 short tons of sodium nitrate, but an overburden of about 100,000 tons would have to be removed in order to extract the caliche containing this nitrate. In the so-called Lower Canyon field 70 acres is estimated to contain 510 tons of sodium nitrate, the recovery of which would involve the removal of an overburden of about 50,000 tons. These two tracts are the largest and best of the ground examined, and, taken together, include 168 acres, which, if workable, might yield 1980 short tons of sodium nitrate, the recovery of which would involve the removal of 150,000 tons of overburden. The result of examinations at other places do not justify estimates of tonnage of nitrate.

The Survey's explorations have led to the following conclusions:

1. The nitrate in the Amargosa district occurs in a blanket of so-called "caliche," about 5 inches in average thickness, which lies about 9 inches below the surface of the ground. The nitrate is accompanied by other salts, chiefly sodium chloride.

2. The soil above and the bedrock below the deposits contain insignificant amounts of nitrate.

3. The high dip and the great thickness of the strata covered by the prospecting make it improbable that deeper beds of nitrate occur in this region.

4. The caliche in general contains an average of less than 2.5 per cent of sodium nitrate, the areal distribution of which is uneven.

5. The Zabriskie field, in which the newly found deposit was reported to lie, contains no commercially valuable nitrate.

6. The Upper Canyon and Lower Canyon fields, the most promising in the Amargosa district, together contain, according to careful estimate, about 168 acres of niter-bearing deposits, which, if worked regardless of cost, might produce about 1980 short tons of refined nitrate.

7. The quantity of nitrate available in the Amargosa district is so small and the cost of production would be so great that the district as a whole can not be regarded as a source of commercial nitrate.

8. No further work on the areas already examined is justified, except, perhaps, that in the nature of purely scientific research.

9. The occurrence of caliche nitrate deposits in the Amargosa district, rather than the usual cave or disseminated deposits, makes it seem possible, though improbable, that really valuable deposits of nitrate may occur elsewhere in the same general region.

10. Prospecting should be continued until all similar deposits in other districts have been tested sufficiently to determine their value.

## Aluminium and Its Light Alloys—II

The Technology of Casting, Hot and Cold Working—Production of Tubes and Foil—Composition of Fluxes and Solders—Effect of Mechanical Work and Heat Treatment on Physical Properties

By PAUL D. MERICA

### VII. TECHNOLOGY.

#### 1. CASTING

**P**RACTICALLY no aluminium is poured into sand or even chill castings today except for the production of rolling or melting ingots. "Aluminium" castings are made of an alloy of aluminium with copper, zinc or other metals; the subject of casting alloys of aluminium is discussed below.

For rolling and drawing aluminium is heated without flux in reverberatory or in crucible furnaces and poured into chill molds. Care is taken in melting to keep the temperature below 800°C; above this temperature the aluminium absorbs gas, oxidizes and a porous ingot may result. The melting is usually done at from 725 to 750°C. Quick cooling in the chill ingot molds is very necessary in order to secure a fine grain, and consequently good mechanical properties, as well as ease of hot rolling. When starting to pour a chill mold for rolling ingots the mold is held at an angle, such that the metal flows down one side and does not splash. During the pouring the mold is continually and slowly tilted in to the vertical position. In this manner cold sheets and similar flaws are prevented.

#### 2. WORKING

Sheet aluminium is usually rolled from one of the standard rolling ingots (see p. —). The ingots are reheated after casting to about 400°C and rolled down hot in from 10 to 12 passes to a sheet,  $\frac{1}{4}$  to  $\frac{3}{8}$  in. thick. This is then rolled cold to gage without intermediate annealing. Sheet as thin as 0.0005 in. may be rolled; this is of course foil. If soft sheet is desired the cold-rolled sheet is annealed, generally at from 375 to 400° C for 18 to 30 hours, and cooled in air.

Rods and wire are first hot rolled and then drawn cold to size, the methods differing but little from those in vogue for copper. Wire for example may be rolled hot from a square section billet weighing about 85 lb. (usually about 4 in. square in section and 5 or 6 ft. long), to from  $\frac{1}{2}$  to  $\frac{3}{8}$  in.; these rods are drawn cold to the wire sizes desired. Sometimes, particularly in European practice, all of the rolling is done cold instead. Tallow is used as a lubricant and the wire may be drawn at from 150 ft. (initial) to 600 ft. per minute final speed.

Tubes are made by the cupping of plates, followed by drawing on the press and then on the standard draw bench; this is done cold with intermediate annealing if necessary.

Sections, rods and tubes are also made by extrusion at higher temperatures, about 400°C, by hydraulic pressure. Sections up to 6 in. in diameter are made in this manner with wall thicknesses of as small as  $\frac{1}{4}$  in. Continuous tubing may be made also by this method.

Aluminium is very readily stamped, drawn and spun; cooking utensils and vessels of various kinds are produced by spinning annealed aluminium sheet. "In thicknesses above No. 20 B. & S. gage, aluminium will take a draw of from  $\frac{1}{4}$  to  $\frac{1}{2}$  more depth than will copper, brass or steel."

Aluminium foil, 0.0005 in. in thickness may be still further beaten into aluminium leaf almost as fine as gold leaf.

Pure aluminium is not readily machined; the metal drags, the tools do not cut but tear; files are "smeared" with the metal. The alloys of aluminium are much more readily machined; particularly the casting alloys. For the metal and its alloys the tool should be sharp with a good clearance, as for wood; the cut should be light and made under a suitable oil such as lard oil or the same mixed with 3 parts of benzine. A cutting speed somewhat greater than that used for brass is suitable.

#### 3. WELDING AND SOLDERING

Aluminium can be both soldered and welded, the latter by several different processes. In both cases a principal difficulty consists in the removal of the layer of oxide before the metal can flow together.

Aluminium may be welded by any of the different commercial processes. Aluminium sheet is generally welded by the oxy-acetylene or oxy-gas torch, the edges being butted for all but light gages, for which they are lapped or flanged. A flux should be used for sheet welding, and consists of a mixture in varying proportions of the chlorides and fluorides of sodium, potassium, lithium, aluminium and calcium. A few typical compositions of fluxes are given in table VI below. These fluxes should be finely powdered and before using moistened down with alcohol.

TABLE VI—PERCENTAGE COMPOSITION OF WELDING FLUXES  
(Pannell, 44, and others)

|   | Sodium<br>Chloride | Sodium<br>Fluoride | Sodium<br>Sul-<br>phate | Lithium<br>Chloride | Potassium<br>Chloride | Potassium<br>Fluoride | Potassium<br>Sul-<br>phate | Calcium<br>Chloride | Cryolite |
|---|--------------------|--------------------|-------------------------|---------------------|-----------------------|-----------------------|----------------------------|---------------------|----------|
| 1 | 30                 | ..                 | 3                       | 15                  | 45                    | 7                     | ..                         | ..                  | ..       |

The flame must not be held so close to the work as in steel welding, and a slightly reducing flame is to be used. A feeding stick of the same composition should be used; if the joint edges are flanged a feeding stick is not necessary.

Castings may be welded in the same manner, except that it is not necessary to use a flux, although results are generally better when it is used. The casting should be well supported so that no stress comes upon the welded joint while it is hot, as the metal is fragile and brittle at a temperature below the melting point.

In welding work on castings, the latter should preferably be pre-heated in order that internal stresses caused by shrinkage are not left in the welded casting when cool.

Arc welding may also be used for repair work on castings, but is not used for sheet and thin work.

Rods and wires are best butt welded by a combined heating and pressure method. The older methods of Heroult and of Cowper-Coles consisted in squaring off the ends of bars, heating these ends to about 400°C and bringing them together and hammering them (Heroult) or under pressure (Cowper-Coles). The electric resistance butt welding machines have however, furnished a much more suitable means of heating and applying pressure than the older processes and are in general use.

Spot-welding of sheet aluminium has been done but does not seem to give as reliable a joint as the oxy-acetylene process.

Welding, chiefly oxy-acetylene, is now quite widely practiced, both on aluminium castings and on sheet. Large numbers of welded aluminium vessels, pans, and containers of various sorts are manufactured each year. The welds are in most cases so perfect that the weld cannot be detected in the finished article. However, the welding of aluminium by any of the above methods is not easy, and requires experience. Welders familiar only with iron and steel work will generally make a complete failure of their first aluminium work.

Although welding is the only process to be recommended for joining aluminium when the joint must have strength and is exposed to the weather, it may in many instances be advisable to solder aluminium articles instead of welding them. The application of solder is easier, requires no especially skilled operator and the temperature of application is not so high as to cause buckling or distortion in the welded piece. On the other hand the metals used in such solders are all electro-negative to aluminium; a soldered joint is rapidly attacked by water or moisture, the joint becoming completely disintegrated in a short time. Only when the joint may be varnished or protected or for very heavy joints where slight corrosion would not be serious should solder be used.

It would be useless to give a list of all of the recommended solders for aluminium now on the market. They consist for the most part of varying mixtures of zinc, tin and aluminium of which Table VII will give some typical examples of those most generally used. Some

mixtures contain copper, lead, bismuth, antimony, and iron, the function of which is certainly not clear; in fact these metals are probably harmful.

Solder is best applied without a flux. The edges of the aluminium are filed clean and tinned with the solder, which should be thoroughly rubbed into the surface with a wire brush or with waste. The joint is then readily made in the usual manner between the tinned surfaces, using an iron if necessary.

#### 4. ELECTROLYTIC DEPOSITION

The deposition of aluminium from a bath of its fused salts has been noted above. The electrolytic separation of aluminium from its aqueous solutions can be effected but the current efficiency is very low and the metal not adherent; it is therefore never done commercially.

The electroplating of other metals on aluminium is of somewhat more importance but this operation is also attended with the greatest difficulty, due to the high chemical reactivity of the metal. The principal difficulties are (1) the thorough cleansing of the surface of the aluminium, and (2) the securing of an initial layer of electro deposited metal which is adherent; aluminium behaves in this respect in a manner much similar to iron.

There are a number of patents claiming the accomplishment of these two operations. The firm, Mix and Genest, have given a great deal of attention to this problem and describe in their patents a number of processes for the preparation of the metal for the plating bath. Some of them are:

- (1) The use of hot or cold sodium hydroxide (NaOH).
- (2) The use of halogen acids with the addition of alcohol, glycerine, etc.
- (3) The use of gelatine in a hot dilute alkaline bath (borax, sodium phosphate, etc.).
- (4) The use of glycerine with potassium carbonate, alkali phosphate, etc.

Canac and Tassilly (260) describe a long process depending on the cleaning of the aluminium with KOH or  $K_2CO_3$ , brushing with milk of lime, dipping in 2% KCN, dipping in a solution (A) of 500 gr. HCl, 500 gr. water, 1 gr. iron, followed by washings and repetition alternately of dipping in solution (A) and water until, as they claim, an adherent coating of iron has been produced upon the aluminium, upon which copper or any other metal must then be deposited in the usual manner.

The present processes for electro plating aluminium are not satisfactory; an adherent layer is not produced. Furthermore the electro deposition of metals upon aluminium as a measure of protection against corrosion is of most doubtful value, since a layer of all metals electronegative to it protects only mechanically, and actually by galvanic action accelerates corrosion, once the layer is pierced, whereas metals electropositive to aluminium are too readily corroded to effect any protection to it. Much better protection is afforded by a varnish or a paint (see above).

#### 5. MISCELLANEOUS

*Finish.* Aluminium is given several types of finish; the two most important are the polished and the satin finish. The former is obtained in the usual manner by buffing with rouge. The latter is obtained either:

(1) by caustic dipping; the metal is cleaned in benzene, dipped in boiling concentrated caustic soda, washed, dipped in hot, strong nitric acid, washed in boiling water and dried very quickly.

or (2) by scratch-brushing; the metal is carefully freed from grease and then brushed on the wire brush wheel.

**Granulating.** Granulated aluminium has been used in the manufacture of steel. It is made by pouring molten aluminium in thin streams into cold water, which is stirred. The metal may for this purpose be poured through a sieve.

**Calorizing.** Ruder (46) describes a process of coating metals with aluminium by heating in a mixture of aluminium and aluminium oxide at higher temperatures. This is accomplished at from 700° to 800° for copper and from 900 to 950° C for iron and steel. The layer formed varies from 0.025 per cent to 0.010 mm. in thickness.

Aluminium has been applied by the Schoop process.

Aluminium powder for painting and the thermite reaction is produced by rubbing foil through a metal sieve under molten fat.

## VII. THE PROPERTIES OF ALUMINIUM AS AFFECTED BY MECHANICAL WORK AND BY HEAT TREATMENT

When aluminium is cold worked the hardness or tensile strength is increased and the ductility or elongation in the tensile test decreased. The manner in which these properties vary with different amounts of cold working is shown in Figure 9, drawn from data

FIG. 9.—EFFECT OF COLD WORKING ON THE TENSILE PROPERTIES OF ALUMINIUM SHEET

kindly supplied by the Aluminum Company of America from tests on cold rolled sheet.

The Shore scleroscope hardness number (magnifying hammer) increases also from 5 to 6 for annealed aluminium sheet, to from 15 to 20 for hard sheet.

Annealing produces a recrystallization and softening of the metal. Only recently, Carpenter and Taverner (207) have made a systematic study of the rate of softening of aluminium sheet, by annealing at different temperatures. They used sheet cold rolled to 0.125 in. (probably from  $\frac{3}{8}$  inch, but the exact amount of cold reduction was not known to the authors), of four materials of the following average analysis: Silicon, 0.75

per cent (0.70 to 0.81); iron 0.34 (0.34 to 0.36); copper, 0.03.

A general idea of the results of their tests is gained from Figs. 10 and 11. The principal facts developed by this investigation are:

(1) The hardness caused by mechanical work is lost very rapidly upon annealing at from 300 to 500°C. The

FIG. 10.—EFFECT OF ANNEALING ON TENSILE STRENGTH OF COLD-WORKED ALUMINIUM (CARPENTER AND TAVERNER)

same final tensile strength of about 12,700 lb. per sq. in. is obtained in all cases.

(2) The softening is most marked within the first portion of the annealing period.

(3) No hardening by annealing was noticed as in the case of copper and brass.

(4) Below 300°C. the decrease in hardness is very slow, but occurs within the temperature range of 100 to 200° with no increase of ductility.

The authors did not study the effect of previous cold reduction on the rate of softening by annealing, but

FIG. 11.—THE ANNEALING OF COLD-WORKED ALUMINIUM (CARPENTER AND TAVERNER)

there is no doubt but that the extent of this reduction has a great effect upon the annealing of the metal, as has been shown to be the case with copper.

Some annealing tests on aluminium tubes are described by Breuil (204).

(To be continued)

## The Deresination of Rubber—II

Description of a Plant for Producing About 400 Tons of Deresinated Guayule per Annum — Specific Gravity Tables for Solvents — Tables for Determining Mixed Solvents.

By ANDREW H. KING

THE deresinating plant of which Fig. 1 is a diagram, was a small one having a maximum capacity of about 400 tons of deresinated Guayule per year. It was housed in a two-story brick and steel building 50 feet wide by 150 feet long, and 32 feet high. Both floors were concrete, carefully sloped to drains placed at frequent intervals. The equipment consisted of two washers, two vacuum dryers, three churns, five kettles, six condensers, a recovery tower, pumps, and numerous tanks. On the first

FIG. 1—DIAGRAM OF A DERESINATING PLANT

floor were the washing rolls and vacuum dryers. The churns were suspended from the second-story floor beams and projected only about a foot into the upper story. Underneath them were large receiving boxes. The rest of the first floor served for storage. Most of the apparatus was on the second floor, the kettles in a row on one side and the churns on the other. The condensers were suspended from the roof trusses. The recovery tower, into which all the condensers, churns, and separator were vented, was placed at one end of the room and the separator at the other. The pumps and most of the valves were situated in the middle of the room. On the roof a cooling device was installed for cooling condenser water. This consisted of many feet of pipe which was kept wet with water. Steam was supplied from the main power plant some distance away.

**Churns.** The churns were cylindrical in shape, with bulged bottoms. They were made of boiler iron  $\frac{3}{8}$  inches thick on the sides and  $\frac{1}{2}$  inch thick on the bottom and top. The capacity of each was about 2300 gallons. The internal measurements were 8 feet deep by 7 feet in diameter. The churn was charged through two iron doors 20 inches in diameter placed in the top, which, when closed, were pressed by screw clamps into special gaskets. Discharge was through a 16-inch gate valve

attached at the bottom. Four pairs of paddles mounted on a 3-inch shaft supplied the necessary agitation. The paddles were 40 inches, 58 inches, 76 inches and 106 inches respectively from the top. The bottom pair were curved so as to produce an upward current in the churn. There were three pairs of stationary paddles which also served to stay the shaft and keep it straight during operation. A 15-hp. motor supplied sufficient power for the three churns. The paddles could be rotated in either direction by means of a clutch. Liquids were pumped into the churn through a 6-inch line entering at the top. By teeing and suitable valves this line also served to carry vapors to the condenser during "steaming off" and to connect the churn with the vent system while treating rubber with the mixed solvent.

Following each treatment with mixed solvent a settling period was always allowed, during which the rubber settled to the bottom of the churn. The supernatant liquid was then pumped off by means of a rather ingenious device. A number of lengths of pipe were connected by swinging joints so that they might be straightened out to almost any desired length. To the end which went down in the tank a "J" shaped affair was attached, as in Fig. 2. The lower legs of the "J" were broad and had a mirror-like polish. The entrance was through an opening in its center. This hole was screened with fine wire, set in after the fashion of down spout guards. By holding an electric light overhead and carefully manipulating the pipes one could pump out the solvent right down to the layer of rubber.

**Kettles.** The kettles should rightly have been classed as pans since they were 8 feet in diameter and but 4 feet high. They were made of  $\frac{1}{2}$ -inch boiler iron and were steam jacketed only on the bottom. The jacket was built to withstand 200 pounds of steam pressure. Each kettle was supported by three brick pillars 12 inches square and 4 feet high. All pans were equipped with still heads. On four of them the head was 18 inches in diameter by 3 feet high. The other, which ran exclusively on acetone and water, had a head 18 inches in diameter by 7 feet high. There was an elliptical manhole, two feet by one foot, in the top of each kettle. Charging was accomplished through a 4-inch line entering at the top. The bottom of the still had a slight slant so that it would drain properly to the 4-inch line opening out at the deepest point. From the top of the still head a 4-inch line carried the vapors to the condenser. The maximum capacity of each kettle was

FIG. 2—"J" SHAPED SUCTION DEVICE

about 1400 gallons, but 1000 gallons was a safe charge. When working properly about 300 gallons of mixed solvent could be distilled per hour.

**Condensers.** The condensers were quite satisfactory when a sufficient supply of cold water was available. The shell of the condenser was 4 feet in diameter by 10 feet long. The pipes were 1 inch in diameter by 8 feet long and were of brass. They were arranged in three compartments and were suitably inclined so that liquid condensed in the first one would flow on through. The top section contained 130 tubes, the middle one 60, and the bottom one 40, making a total of 230 tubes. Vapor coming from the still entered the top section; part of it was condensed, and flowed by gravity into a compartment which connected with the middle section. After flowing through the middle section the liquid and uncondensed vapor entered another compartment from which it passed into the bottom section. Cold water was kept circulating around the tubes within the shell. Vapor entrance was effected through a 4-inch line; condensate exit was through a 3-inch line. Water lines were 3 inches in diameter. A vent pipe connected the lower section with the recovery tower, thus maintaining atmospheric pressure in the condenser.

The condensers did not work properly when the temperature of the cooling water rose above 17° C., so about 1000 feet of 2-inch pipe was arranged in coils on the roof, over which water was kept constantly spraying. Each kettle had its own condenser, while but one was required for the three churns.

**Separator.** For separating mixtures of acetone and water from acetone and gasoline an apparatus similar to an ordinary separatory funnel was employed. It consisted of a cylinder 5 feet in diameter by 8 feet in height, with a truncated cone 2 feet long at the bottom. The lower section of this cone was 1 foot in diameter. At this point a section of pipe 1 foot in diameter by 2 feet long was attached. Gage glasses were arranged so as to interlock, and one could follow the line of separation all the way from the top to the bottom. The separator was made of ½-inch boiler iron and was supported by means of brackets resting on

brick pillars. Charging was accomplished through a 4-inch pipe entering at the top. A vent pipe opening into the recovery tower was provided at the top. At the bottom were four different lines for carrying acetone-gasoline, gasoline, acetone and acetone-water to and from their respective tanks. The capacity of the separator was approximately 1000 gallons.

**Recovery Tower.** All churns, the condensers, and the separator had vent lines opening into the recovery tower, thus maintaining atmospheric pressure throughout. This apparatus consisted essentially of a 20-foot stack of boiler iron ½ inches thick, 2 feet in diameter, with a cylindrical receptacle at the bottom which measured internally 4 feet in diameter by 5 feet deep. The vent line (a 4-inch line) entered the column at the top of the lower receptacle. From the top of the stack a very fine spray of cold water was kept constantly falling. A 3-inch pipe opening from the top of the stack gave access to air. Discharge was through a 3-inch pipe opening a little above the bottom of the lower receptacle. A trap was placed in this line a short distance past the column. Gage glasses were provided for the lower receptacle only. The fine spray of water was particularly efficient in washing out uncondensed acetone.

**Fittings.** All pipe was made of extra heavy wrought iron with flange couplings. At necessary places sight boxes were provided, in which hydrometers were placed so that one could watch the flow of liquid and note the change in specific gravity. Three double-acting steam pumps furnished the necessary suction for the whole plant. There were ten large cylindrical tanks of 6000 gallons capacity each buried in the earth a short distance from the building.

**Solvent.** The solvent used for deresinating Guayule, Pontianack, Borneo, Palembang, etc., was composed by volume of 53 per cent acetone (98 per cent) and 47 per cent gasoline. The acetone used had a sp. gr. of .8041 at 15.5° C., and the gasoline was the grade known as 70 to 72° B., the specific gravity of which varies from .6981 to .7000. The grade in use at that time was obtained from Pennsylvania petroleum; practically all of it evaporated below 130° C. Spontaneous evaporation in the open air left no trace of that objectionable oil residue so prevalent now. Some data on the specific gravity of acetone and water mixtures are given in Table II. The percentages of gasoline

and acetone given above mix perfectly. The specific gravity of the mixed solvent is .755. Table III contains corrections for specific gravity of acetone at different temperatures.

**Method of Operation.** Churns of the size described above require a charge of 1200 pounds of Guayule or 5000 pounds of Ponti. The necessary amount of rubber

is weighed up, then put through the cold washing rolls. With Guayule, no attempt to sheet was made, and no water was used. The rubber was only coarsely broken down. With Ponti, water was employed and the pieces allowed to drain off as much as possible before charging. The partly broken down Guayule was taken to the charging floor, the churn was made ready by closing the 16-inch valve in the bottom, opening the valve to the vent line and by closing all steam lines. The churn was then pumped one-fourth full of the mixed gasoline and acetone solvent, previously adjusted to the correct proportions. Then the paddles were started and the charge dropped in, after which the churn was filled within 6 inches of the top with solvent. The manholes were closed and the churn left running on the first treatment which lasted 2 hours, when it

steam line opened. "Steaming off," as it was called, was continued until nothing but water or water with a thin film of oil appeared at the sight box, at which time the hydrometer reading rose to 1000. When this occurred, the charge was ready to be dropped. The large valve at the bottom was opened, the paddles reversed, and a stream of water played on the rubber through the manhole. The charge fell into a large zinc-lined box placed underneath the churn. After cooling sufficiently the rubber was taken out, washed with water on the washing rolls, and sheeted. Drying was accomplished by means of a vacuum dryer.

The schedule of treating was as follows:

|                  |            |
|------------------|------------|
| First treatment  | 2 hr.      |
| Settle           | ½ hr.      |
| Pump Off         |            |
| Second treatment | 1 hr.      |
| Settle           | ½ hr.      |
| Pump Off         |            |
| Third treatment  | 1 or ½ hr. |
| Settle           | ¼ hr.      |
| Pump Off         |            |
| Fourth treatment | 1 or ½ hr. |
| Settle           | ¼ hr.      |
| Pump Off         |            |
| Steaming         | 4 to 5 hr. |

The actual time per cycle was about 10 to 14 hours, because of the time required for pumping out the respective charges and for discharging. About four charges were handled with the three churns running the full 24 hours. Fig. 3 is a diagram of the operation of the process described above.

With 1200 pounds of Guayule as a charge, the mixed solvent required for the first treatment was 1800 gal-

was stopped and the rubber allowed ½ hour to settle. The "J" shaped pipe was screwed into the suction line and the resin-laden solvent pumped into the acetone-gasoline-resin tank, where it remained until ready to purify. The churn was again filled with solvent and run for 1 hour, settled ½ hour, and pumped out as before into the acetone-gasoline-resin tank. The rubber was given two more treatments of either 1- or ½-hour duration with 15-minute settling periods between. The first and second treatments removed most of the resin. The third and fourth were largely diluting and purifying treatments and carried but little resin, so this solvent was used over again in the first and second treatments of the next charge.

After four lots of solvent had been pumped out, water was added in order to precipitate the rubber, and matt it together. The vent line was closed and the

FIG. 3—CYCLE OF OPERATIONS

lons, and for all others about 1400 gallons, making about 13,000 gallons mixed solvent required per day. The solvent losses did not usually run over 44 gallons of gasoline and 15 gallons of acetone per 1000 pounds of rubber produced. With Guayule the yield of dry rubber was seldom more than 55 per cent of the weight of the charge. This was because the rubber was not washed and dried before deresinating. It was found more satisfactory to merely mill the gum until it was partly broken down and dry it by means of solvents.

The high washing loss of Guayule, about 20 per cent. was also a factor. The maximum daily output of deresinated rubber was about 2600 pounds.

In view of the large quantities of liquids required it is obvious that much depended upon the skill with which the plant superintendent refined his solvents. If he grew careless, he might lose enough to completely wipe out the profits. The liquor from the first and second treatments was pumped with the dissolved resin to the proper tank. From here it went to a kettle where the gasoline and acetone were distilled off and the condensate piped to its tank. The resin of Guayule, being fluid, was also pumped to a tank. The liquor from the third and fourth treatments, being fairly pure, was used in the first and second treatments on the next charge. The condensate from the steaming-off operation consists of gasoline, water, and acetone. This mixture was pumped to the separator and allowed to come to equilibrium. The top layer consisted of gasoline and acetone and the lower of acetone and water. The quantity of acetone in the gasoline depended upon the amount of water present. The acetone and water, and acetone and gasoline were carefully drawn off and piped to a separate container.

No attempt was made to separate the acetone from the gasoline in the acetone-gasoline mixture. This cannot be done by distillation since they form a minimum boiling point mixture. It can only be accomplished by adding sufficient water and allowing the gasoline to rise to the top. Separation of acetone from gasoline was unnecessary since it was much simpler to add either acetone or gasoline to bring the mixture to the correct proportions. The acetone-water mixture was fractionated in the kettle with the tall still head, which was kept running entirely on this work. The acetone thus obtained was piped into the acetone storage tank and was drawn upon for balancing the solution to the proper concentration. Whenever gasoline was required it was supplied from storage tank.

The resin-laden solvent from the first and second treatments on distillation always gave a mixed solvent of about the proper concentration. Very little adjustment was ever required. But the acetone-water and acetone-gasoline condensate from the steaming-off operation was a different matter. The water removed acetone from the gasoline, thus making the top layer rich in gasoline and poor in acetone. The acetone content was determined by an indirect method, which arrived at the gasoline content first and that of acetone by difference. A 10-cc. sample of mixed solvent was drawn from the separator and placed in a 15-cc. graduated tube, which was filled to the 15-cc. mark with water and the tube well shaken. It was then placed in an ordinary urine analysis centrifuge and whirled about a minute. The acetone-water solution was removed from the bottom of the tube by a pipette. This was repeated once more. Ten cc. of water were then added, mixed, and whirled again. The reading above the 10-cc. mark, that is the gasoline layer, readily gave the gasoline content. The percentage of acetone was obtained by difference. In order to make use of this mixed solvent, one had only to solve a simple algebraic problem: Given a certain volume of mixed solvent  $V$  consisting solely of acetone and gasoline; let the percentage (by volume) of acetone in the mixture

be  $a$  which is determined; required (case 1) the quantity  $x$  (in gallons) of acetone to be added when the mixture contains less than 53 per cent acetone and (case 2) the quantity  $y$  of gasoline required when the acetone content is greater than 53 per cent.

$$\begin{array}{l} \text{Case 1.} \\ aV - x = \frac{.53(V - x)}{V} \\ .47x = \frac{.53V - .53x}{V(.53 - a)} \\ x = \frac{.47}{.53 - a} \end{array} \quad \begin{array}{l} \text{Case 2.} \\ (1-a)V + V = \frac{.47(V + y)}{V} \\ .53y = \frac{.47V + .47y}{V - .53} \\ y = \frac{.53}{.53 - a} \end{array}$$

Obviously the shift foreman of a deresinating plant could not stop to work out each separate problem, so his requirements were estimated beforehand and the quantities are recorded in Table IV.

The successful operation of a deresinating plant calls for eternal vigilance on the part not only of the foremen and superintendent but of every one concerned. All lines, tanks, kettles, condensers, etc., should be plainly numbered and a chart framed in a convenient place where the operation going on in any one is clearly indicated. All valves should have "open" and "closed" signs, and the purpose of each one clearly indicated by a tag wired to the wheel. A good rule is to keep all valves closed when not in use. The operation as above outlined is far from foolproof and a careless man can destroy a month's profit by one thoughtless act. Leaks of all kinds are to be very carefully watched for. The solvent loss is plenty high enough under the best of conditions without being increased by leaks. The greatest foe of successful operation is carelessness, of which the following is an example. A certain plant did not show a profit over a whole year, notwithstanding the fact that it was running at maximum capacity and apparently as efficiently as possible. Upon investigation it was found that through a mistaken idea on the part of a laborer they were sending about 1000 gallons of acetone each month into the sewer.

## IMPROVEMENTS

**Churns.** These were about as efficient as can be expected of any intermittent process. Personally, I prefer continuous counter-current extraction, pumping the solvent from churn to churn. During steaming off there was a tendency for rubber to be carried into the condenser. Later this was prevented by installing a trap. Steaming off was not entirely a harmless operation. The heating brought about more or less depolymerization of the rubber, but at that time it was necessary in order to remove all the solvent. Vacuum distillation at a low temperature would give a much better product without the trouble of foaming.

**Kettles.** The kettles would have been more efficient if they had been steam jacketed around the sides. There was often a tendency to foam, which was particularly noticeable with Palembang. The use here of one of the modern kettles would greatly aid the efficiency of the plant. A vacuum kettle might help.

**Condensers.** The condensers functioned fairly well as long as there was plenty of cold water. The acetone still should have had a larger condenser, since there was hardly enough cooling surface to condense all the vapor when the still was working at maximum capacity.

**Recovery Tower.** The recovery tower was really a make-shift intended to catch uncondensed acetone, which unfortunately was no small amount. Its efficiency would be improved by filling the tower with any standard tower packing, thus increasing the surface.

**Separator.** Instead of the gravity separator described above, a centrifuge could be used to advantage.

Any chemical engineer can now suggest a number of sensible improvements. Deresinating practice will likely be almost entirely revised in the next few years.

## USES OF RESINS

Because of the scarcity of Ponti and related rubbers, their treatment was not given any particular discussion above. However, Ponti resin has certain uses. Being unsaponifiable it makes an ideal varnish for concrete. Pontiniack rubber and resin have been used in chewing gum. The products formed by dry distilling the resin are useful as a rubber substitute in cheap stocks.

Guayule resin is hard to dispose of, but is of value when added in small amounts to cheap stocks containing dry shoddies where its effect is that of a softener.

## CONCLUSION

The purpose of the writer in preparing this paper has been to set forth something of our knowledge of rubber resins and to revive interest in deresinating, which is now almost a lost art. In view of our efforts in the war the deresination of Guayule will no doubt be resumed within a short time.

Current prices in platinum are no indication of its former value. At one time the crude grains mixed in with the ore of certain gold mines in Colombia, South America, were regarded as a waste product and thrown away. The extent of recovery of this metal may be store, recovering enough platinum to enable him to be instanced by the case of one man who tore down his rebuild on a larger scale, and clear \$4,000 in American gold besides.

## Regulations Governing the Sale and Exportation of Caustic Soda

The U. S. War Industries Board and the War Trade Board jointly announce that on and after August 1, 1918, manufacturers of caustic soda in the United States will not enter into any contract for the sale of caustic soda with any person in the United States for the purpose of exporting the same, unless and until advised by the prospective purchaser that a United States export license covering such caustic soda has been duly obtained and the number thereof is furnished.

Manufacturers will not sell on and after the above mentioned date, caustic soda for domestic consumption unless the purchaser agrees not to export same nor to sell same for export, and if it is resold in the domestic market, to exact or cause to be exacted a similar agreement from each and every subsequent purchaser.

On and after August 1, 1918 the War Trade Board will not license for exportation caustic soda to any destination until the applicant complies with regulations contained in Ruling 175, copies of which can be obtained on application to any branch office of the War Trade Board.

## Patent Office Needs Technically Trained Persons

The Commissioner of Patents, Washington, D. C., announces the need of technically trained persons for the examining corps of the Patent Office. Men or women are desired who have a scientific education, particularly in higher mathematics, chemistry, physics, and French or German, and who are not subject to the draft for military service. Engineering or teaching experience in addition to the above is valued. The entrance salary is \$1500.

Examinations for the position of assistant examiner are held frequently by the Civil Service Commission at many points in the United States. One is announced for Aug. 21 and 22, 1918. Details of the examination, places of holding the same, etc., may be had upon application to the Civil Service Commission, Washington, D. C., or to the patent office.

Should the necessity therefor arise temporary appointments of qualified persons may be made pending their taking the Civil Service examination. Application for such appointment should be made to this office.

## Combustion Engineers Wanted

The Bureau of Oil Conservation, Oil Division, U. S. Fuel Administration, desires to secure a combustion engineer for each of the districts named below, who will act as inspector of all plants within the district using fuel oil and natural gas: Boston, Providence, New York City, Philadelphia, Pittsburgh, Buffalo, Detroit, Chicago, Minneapolis, Tulsa, New Orleans and San Francisco. It is desired that these men shall act as volunteers. The Administration will pay a reasonable compensation for men who cannot give their services for nothing. Only those who have had experience in the combustion of fuel oil and natural gas would be of value to the Administration. Application can be made to W. Champlain Robinson, Director of Oil Conservation, Oil Division, United States Fuel Administration, Washington, D. C.

## Recent Chemical and Metallurgical Patents

**Manganese Dioxide Depolarizer.**—In the preparation of a depolarizer with good electrical conducting qualities suited for use in dry batteries, MESSRS. CARLETON ELLIS and ALFRED A. WELLS of Montclair, N. J. (assignee, National Carbon Co.) patent the process of oxidation of manganese sulphate or chloride with hypochlorite in weak acid solutions at boiling temperatures. In strongly acid solutions, very little precipitate is obtained and in alkaline, the manganese is precipitated as brown manganic hydroxide and thus rendered unreactive with the free oxygen of the hypochlorite. When the sulphates are used, an excess of acid soon accumulates, which retards the reaction in proportion to its concentration; this excess acid is neutralized with sodium carbonate or basic manganese salts. In the case of the chloride salts, hydrochloric acid is volatilized to such an extent that either some of it must be condensed and returned to the solution or a slight amount of sulphuric acid or manganese sulphate must be added to maintain permanent acidity. With from  $\frac{1}{4}$  to  $\frac{1}{2}$  per cent acid content, a quantitative yield is claimed with a mixture of 10 volumes of 44 per cent manganese chloride, 25 volumes of 30 per cent sodium hypochlorite, 11 volumes of 10 per cent hydrochloric acid, and 9 volumes of water. (1,269,914, 1,269,915; June 18, 1918.)

**Aluminium Chloride.**—The price of aluminium chloride has been relatively high due to difficulties in getting suitable materials for furnace construction resistant both to high temperatures, carbon and chlorine. On this account, it has been more economical to burn high priced metallic aluminium in chlorine gas than to use a crude source of material such as bauxite.

MESSRS. GEORGE H. KING and GERALD I. ROBERTS of Port Arthur, Texas (assignee, Gulf Refining Company) patent the process of passing a finely ground mixture of carbon and alumina, which has been heated to a very high temperature in a separate furnace, through an atmosphere of chlorine. The reaction,

takes place with a maximum surface of reaction; dust impurities are removed mechanically before the aluminium chloride has condensed. Spent oil catalyst can be regenerated by this process, the product being oiled with kerosene to prevent hydrolysis with atmospheric moisture during the grinding process. (1,268,015; May 28, 1918.)

MESSRS. DILLON F. SMITH and HARRY ESSEX of Pittsburgh, Pa. (assignee, Gulf Refining Co.), patent the reaction between aluminium carbide, sulphide, etc., and chlorine or hydrochloric acid, which they state takes place as low as 200 deg. C. in an iron retort, the walls of which should be kept sufficiently cool to prevent the chlorine from reacting with the iron. (1,270,226; June 18, 1918.)

**Silica Fuse Filler.**—For the manufacture of a silica powder of low apparent gravity, weighing from 12 to 30 pounds per cubic foot, MESSRS. W. C. ARSEM and J.

G. E. WRIGHT of Schenectady, N. Y. (assignee, General Electric Company), patent the process of adding one part of 1.45 sp.gr. water glass to three parts of water and mixing with a solution of one part of ammonia chloride in eight parts of water, whereupon colloidal silica is precipitated in a very fine state having the approximate composition of  $SiO_2 \cdot NH_3 \cdot H_2O$ . The ammonia and water are removed from this precipitate by prolonged boiling and calcination of the filtered and washed hydrated silica.

**Manufacture of Ammonium Phosphates.**—INGENUIN HECHENBLEICKNER of Charlotte, North Carolina, has discovered that for the production of mono and di-ammonium phosphate the best concentration of phosphoric acid is from 35 to 43 per cent  $P_2O_5$ , the actual optimum varying with the purity of the acid and the heat insulation and the size of the apparatus. Fig. 4 shows this acid in tank 1, from whence it is distributed and trickles down the filling of tower 4, there absorbing a counter current of hot ammonia gas entering the system at 16. The resulting phosphate is further warmed by the considerable heat evolution of the reaction, and trickles through pipe 5 into the tube 7. Any remaining acid is neutralized by the ex-

FIG. 1.

cess ammonia at this point, and crystallization starts immediately. The mixture is further dried by the steam jackets 8 and 9. The result is that in one continuous operation the inventor is enabled to produce mono and di-ammonium phosphate of a fine, dry, crystalline nature, stable and non-hygroscopic. In some cases the crystallizing tube may be replaced by a tank of water where the salts crystallize and are removed from time to time, centrifuged and steam dried if necessary. When di-ammonium phosphate is to be produced the solution in the saturation tank should be saturated hot until it has a slight ammonia odor. Di-ammonium phosphate is less soluble in hot water than in cold water and furthermore hot precipitation prevents the formation of tri-ammonium phosphate and gives a continuous crystallization of pure di-ammonium phosphate producing a fine, crystallized, stable, non-hygroscopic product. (Assigned to Southern Electro-Chemical Co., 1,264,513 and 14, Apr. 30, 1918.)

**Operation and repair of Kjellin Refining Furnace.**—DAVID R. KNAPP, of Pottsville, Pa., patents a device whereby the ordinary Kjellin furnace is placed on a circular plate capable of receiving a slight tilt, and

being slowly rotated simultaneously. In operation, the furnace is kept on a level keel at a normal temperature for the elimination of silicon and phosphorous. When these impurities are sufficiently reduced, the base plate is slightly tilted, thus contracting the area of the molten conductor at the high side. The metal at this point is therefore highly superheated with practically the normal power input; rotating the base plate changes the location of the superheated metal continuously, and the refining of the sulphur, manganese and carbon is thus effected. After tapping, the furnace may again be tilted to collect the molten conducting ring at the lower portions of the channels, when the entire furnace bottom may be inspected and repaired before proceeding with the next charge. (1,240,460; Sept. 18, 1917.)

**Alloy for Electric Resistance Elements.**—The ohmic effect of titanium in alloy compositions is the basis of a patent by WILBUR B. DRIVER of East Orange, N. J. Mr. Driver gives the following list of alloy compositions with the determination of the specific resistance for each:

| No.       | Percentage Composition |          |          |      |           | Specific Resistance |
|-----------|------------------------|----------|----------|------|-----------|---------------------|
|           | Nickel                 | Chromium | Titanium | Iron | Manganese |                     |
| No. 1...  | 75                     |          | 6        | 19   |           | 77                  |
| No. 2...  | 68                     | 15       | 4        | 11   | 2         | 117                 |
| No. 3...  | 65                     |          | 8        | 27   |           | 96                  |
| No. 4...  | 65                     |          | 6        | 19   | 10        | 106                 |
| No. 5...  | 60                     | 12       | 1        | 24   | 3         | 112                 |
| No. 6...  | 60                     | 12       | 6        | 19   | 3         | 125                 |

The advantages of these alloys are high melting points, durability and resistance to oxidation at high temperatures. The amount of titanium that can be used is limited only by the mechanical properties desired for drawing into wire and rolling into bars. Pure titanium is not a commercial product and even were it available, it would have too high a melting point for direct alloying purposes. Nickel-titanium and ferro-titanium are the present sources of supply. Owing to the relatively low specific gravity of titanium, it has a tendency to float, so that care should be exerted to entirely submerge it into the molten metals of the alloy. (July 30, 1918.)

**Ammonia Sulphate.**—A method of air oxidation of ammonia sulphite is patented by MESSRS HEINRICH DANNEEL and EMIL KUHN of Basel, Switzerland. The feature of their process is that calcium sulphite is formed according to the reaction:

In this way the loss of ammonia is prevented as well as the formation of an acid free ammonia. (1,274,247; July 30, 1918.)

**Cleaning Metals.**—When silver, gold, etc., are placed in an electrolyte in contact with an electro-positive metal such as zinc, aluminium, etc., nascent hydrogen forms on the silver under enormous pressure and either pushes off all foreign matter or reduces it, so that a clean metallic surface is produced. Sodium bicarbonate was used first probably because some woman accidentally dropped a silver spoon into an aluminium dish contain-

ing it, and discovered the "magic" way of cleaning silver. MESSRS. CHARLES B. MOREY and C. J. HUBER of Buffalo, N. Y., have found an improved electrolyte for this process in a slightly acidified solution of sodium chloride. Three per cent salt with one-tenth of one per cent hydrochloric acid is their preferred solution. The acid keeps the contact between the two metals clean besides furnishing more active ions. (1,274,186; July 30, 1918.)

**Calcium Sulphite.**—As an aid to the conservation of sulphur, MESSRS. HENRY HOWARD of Brookline and FRANK G. STANTIAL of Melrose, Mass., of the Merrimac Chemical Company, have developed a process for extracting sulphur dioxide from flue gases in the form of calcium sulphite, which can well be used as an intermediate for the manufacture of sulphite liquor for wood pulp manufacture. The flue gases are passed through sodium hydroxide solution, the  $SO_2$  reacting with the carbonate formed and the solution being regenerated as follows

Gas with as low a content of  $SO_2$  as 0.75 per cent has been successfully reduced to 0.10 per cent by this process. (1,271,899, July 9, 1918.)

**Lead Arsenate.**—The reaction between litharge and arsenic acid is greatly accelerated in the presence of hydrofluosilicic acid which dissolves the lead and thus furnishes an abundance of lead ions to react with the arsenate. The reactions are:

MR. I. P. LIHME of Lakewood, Ohio, in his patent specification, states that as small an amount as 1/200 equivalent of  $H_2SiF_6$  produces this reaction giving a soft, flaky, white precipitate that is admirably suited for insecticide spraying solutions. In the older methods of preparation, where arsenic acid acts directly on the solid litharge particles, the precipitate of lead arsenate forms a crust on the lead, which is a less efficient insecticide. (1,267,428; May 28.)

**Calcium Carbide.**—An improvement in the form of the carbon used in producing calcium carbide is patented by MR. ROBERT RUSSEL of Chicago, Ill., in which a 94 per cent fixed carbon hard pitch coke is thoroughly mixed with lime. Calcium carbide of ninety per cent purity is reported as obtained, which is a fraction better than the coal coke product. The acetylene gas obtained upon hydrolysis of this pitch carbide is free from many of the usual impurities, an important factor where this gas is to be used in the chemical synthesis of alcohol, acetic acid and acetone. (1,271,229, July 2, 1918.)

**Sodium Hydrosulphite.**—The reduction of sodium sulphite solution with hydrogen under high pressure as a substitute for zinc is patented by MR. A. K. GYUANDER of Westbrook, Maine. The reaction is simple:

It is found that the velocity of the reduction varies with the pressure of the hydrogen, 100 lbs. per sq.in. pressure bringing about a 95 per cent conversion in 352 hours; 1456 lb., 24 hours, etc. (1,270,150, June 18, 1918.)

### Automatic Soldering Iron Rack

THE Cutler-Hammer Manufacturing Co. of Milwaukee have recently developed an automatic soldering iron rack and temperature control panel which decreases the amount of current taken by the iron while maintaining the working temperature. The rack consists of a small slate panel arranged for mounting and carrying a support for the soldering iron, which turns the elec-

tric current through a resistance circuit when weighted down. Taking the weight of the iron from the hook disconnects the resistance from the circuit and allows the full current to flow. A push button snap switch gives a convenient way of turning the current off and on without removing the soldering iron plug from the panel.

### The Thomas Gas Meter

IN THE present day of fuel conservation, bee-hive coke ovens are passing out and to a great extent coke gas is coming into use. In view of this, the Thomas meters manufactured by the Cutler Hammer Co. of Milwaukee, with a capacity of 500,000 cu. ft. per hour,

are an extremely interesting development. They embody the principle that, with a constant gas mixture, the specific heat is a function of its trade measurements. In the accompanying illustration Fig. 1 a sectional view of the gas main shows the arrangement of the electric resistance heating coil and the thermocouples. A differential of 2 deg. F. is maintained by means of the galvanometer control. The heat required to maintain

this temperature is measured by the current consumed through the watt meter, illustrated in Fig. 3, which, however, is graduated to 1000 cu. ft. of gas. A graph

Fig 2

Fig 3

meter is also placed in the circuit, giving a time record of the rates of gas flow, Fig. 2. Daily gas analyses are made to check any variation in specific heat due to varying contents of hydrogen, methane, carbon monoxide, etc., and it is reported that no serious error arises from this source.

### Electrical Controlling Pyrometer

THE most precise electrical measurements are those made by a zero or balance method, such as the Wheatstone bridge and the potentiometer. In both no current flows through the galvanometer at the moment when the measurement is made and hence galvanometer errors are excluded. In the potentiometer, variations in the resistance of lead wires and of the source of electromotive force, such as a thermocouple, are also eliminated, the lead wires and thermocouple being in the same circuit with the galvanometer.

Zero methods, however, require external power for the balancing of the circuit. For single measurements this power is ordinarily supplied by the hand; a contact is moved along a slide wire or resistances are plugged in or out until the galvanometer comes to the zero position, when the quantity to be measured is at once known from the amount of resistance that has been used. The Leeds & Northrup Co., of Philadelphia has developed a line of power-driven recorders, however, in which the adjustments are made automatically, the galvanometer merely determining in which direction the adjustment is to be made.

Early attempts to use a galvanometer for this purpose were along the line of having the boom or pointer of the galvanometer close an electrical circuit. This, however, proved unsatisfactory, as with low voltages on the boom, contact would not be made through particles of dust, while with a higher voltage the boom would "freeze" or fuse to the contactor. In the Leeds & Northrup apparatus the boom serves merely as a mechanical trigger. A reciprocating part, kept in constant motion by a motor, is arranged not to strike the boom when the latter stands in the no-current position, but when the boom moves out of this position in either direction, the reciprocating part pushes it against another part which adjusts the bridge or potentiometer circuit, the amount of the adjustment being regulated according to the distance which the boom has swung, that is, to the unbalancing current through the galvanometer.

The power of the motor is sufficient, not only for making the adjustments, but also for the operation of the chart drum or roll. For this purpose, however, the motor must run at a constant speed, that is, sufficiently constant to give good time-keeping qualities, since the abscissae of the chart are laid off in hours and minutes. This has been found to necessitate the use of a special

FIG. 1.—RECORDER OPEN FOR EXAMINATION

governor, and much time and research have been devoted to this problem. The governor finally adopted is of the centrifugal type and operates by opening and closing a shunt in the field circuit. When the motor is in operation this contact is continually on the make and break, as may be easily detected by listening to a telephone receiver connected in the circuit.

The motor not only adjusts the movable contact of the bridge or potentiometer, but also supplies power to move the recording pen. Multiple recording instruments which will record for a number of different thermocouples or resistance thermometers are also built. In these the motor operates the selector switch which connects the recorder to the different circuits and simultaneously turns a printing wheel which impresses upon the record sheet a dot to record the reading, and a number to identify the circuit which is being measured.

In the heat treatment of metals, it is becoming more and more the practice to bring the leads from thermocouples in different parts of the furnace and in different furnaces to a central control station. This is facilitated by the introduction of base metal thermocouples, which permits of the prolongation of the couple itself to the measuring instrument, where the effects of temperature upon the cold end of the couple are readily compensated for, and by the adoption of the potentiometer method of measurement, with which differences in resistance of lead wires become immaterial. An attendant at the control station uses an indicating instrument, which he connects successively to different thermocouples. Usually he is also provided with switches, by means of which he can light signal lamps for the guidance of the operators at the furnaces, usually a red light to indicate too high a temperature, a blue one to indicate too low a temperature and a white one to indicate the right temperature. A multiple-point recorder is generally installed to record the different temperatures automatically, one after the other. The Leeds & Northrup Multiple Recording Instruments, for example, are built for as many as 16 different circuits.

Where it is preferred to have the signaling at the furnace done automatically, a Leeds & Northrup "single-point" or curve-drawing recorder is provided with contacts on the moving element by means of which the signal lamps will be lit, accordingly as the temperatures in the furnace are too high, too low, or correct. An interesting extension of this plan is to use two thermocouples in different parts of the furnace and to provide the recorder with a commutator by means of which it reads first on one and then on the other. The chart produced is a single line running alternately back and forth between the two temperatures and indicating the temperature difference graphically. At the same time the commutator controls a fourth signal lamp at the furnace to show which thermocouple is being measured.

The double recorder is thus suitable for demonstrating uniformity of furnace temperatures, or the lack of it. It shows graphically the effects of empty furnace, full furnace, or part full furnace, and how distribution of heat is affected by rates of firing, location of load, door and other losses, cold hearth, etc. It is a convenient means for investigating furnaces and showing how errors may be overcome by moving burners, baffles, or arches, or changing the method of introducing heat, as by the use of side burners, underfiring, overfiring, number of burners, position of doors, etc. It also shows definitely the effects of location of thermocouples, how the readings vary according to their placing with respect to the work and the burners, also the number of couples to be used in a given furnace, etc.

The use of this double recorder has exploded the old "soaking heat" idea, since it demonstrates that it is practically impossible to bring many kinds of loads up uniformly to the desired temperature by holding the

FIG. 2.—INSTALLATION WITH TWO THERMOCOUPLES

furnace at a "constant" temperature, without underheating some parts, and overheating others. This type of equipment has been found of especial value in studying the heating of different kinds and sizes of sections or numbers of pieces, different methods of loading, speed of loading and unloading, mechanical furnacing, the heat treatment of large single pieces, such as gun forgings, etc.

Atomizing Nozzle

IN THE mixing of corrosive chemicals, which must be brought together slowly because of their heat of reaction, etc., such as in nitrating, unsaturated coal-tar oils,

sulphur-chloriding oils for making rubber substitutes, etc., a recently developed stoneware nozzle placed on the market by the Monarch Manufacturing Works of 3129 Emery St., Philadelphia, Pa., will find a ready demand. As shown in the accompanying illustration, the upper part is a metal socket of lead or any desired metal or ma-

that provision be made to prevent the turning of the valve stem at the time of seating, a requirement provided for in this valve which insures a uniformly wearing plug and seat. The threads for operation are in a grease-packed casing in the handle. The valve can be packed under pressure, as a packing gland is adjusted

DIAGRAM OF ATOMIZING NOZZLE

terial for attaching the nozzle to the conductor of the liquid, into which the stoneware nozzle screws tightly against a gasket. The outside of the nozzle is conical, insuring a wedge fit in cases where it is desired to induct the spray through a terra cotta wall. The gyratory action, which produces the spray, is made by forcing the liquid through the two grooves *G*, which is then reflected radially by striking the walls of the eneral recess *R*, out through the nozzle opening. The rate of flow of the liquid will depend on its viscosity. For water, one gallon per hour for each 10 pounds per sq.in. of pressure may be figured, and for other liquids, the viscosity ratio can be applied for estimating purposes.

### Valves for Corrosive Liquors

THE weakest point in any valve, and especially in one for corrosive liquids, is the valve seat. The lead valves manufactured by the Chemical Equipment Company, Chicago Heights, Ill., have a double faced seat, which can be taken out, reversed or redressed without dismounting the valve body. The seat is provided with a straight cylindrical hole in the center and the tapered plug meets this in a single line contact. A feature of the line contact on a tapered plug is that, should there be a scale formation on the plug, the act of seating will crack off the scale and give a tight closure.

Lead being a comparatively soft metal, it is essential

VALVE FOR CORROSIVE LIQUORS

by means of a sleeve operating within the upper part of the yoke, the threads of which are grease packed.

#### GENERAL DATA ON LEAD VALVES

|                              |           |         |

### Gas Rivet Heaters

Gas is to be used exclusively for rivet heating, plate bending and general fabricating heating purposes hereafter at the Bethlehem Shipbuilding Corporation's Alameda plant. This is a radical departure from the ship-building methods that have been in use for years, whereby it was thought that only coke could be used—even oil was considered an innovation. Good work by a riveting crew depends to a great extent on properly heated rivets. With a continuous and uniform gas forge, the heater man can give his undivided attention to regulating the forge so that there will be no burned nor underheated rivets, irrespective of the speed at which the crew works. This tends toward regularity, with properly upset and tight, full-headed rivets as a result. The cooling contraction is likewise more uniform and caulking is reduced to a minimum.

## Synopsis of Recent Chemical and Metallurgical Literature

**Combustion of Producer Gas.**—V. HASSREDTER, in *Metall. und Erz.* Vol. XV, page 139, gives calculation formulae for the excess of air used in combustion of producer gas. When a volume,  $G$  of producer gas is burned, the volume of air,  $L$ , required is not  $R - G$  as commonly stated, but  $R - G + c - d$ , where  $R$  is the volume of products of combustion,  $c$  the contraction and  $d$  the contraction due to combustion. For each volume of each of the following gases, when dry, the respective values of  $c$  are:  $C_2H_4$  or  $C_2H_2$ , 2.5;  $CH_4$  or  $C_2H_6$ , 2.0;  $H_2$  or  $C_2H_4$ , 1.5;  $CO$ , 0.5. When the volume of the moist products of combustion is taken, neither expansion nor contraction occurs in the combustion of methane and ethylene; hydrogen and acetylene contract 0.5 vol.; but with ethane and benzene, expansion ( $d = .5$ ) occurs. If  $L_0$  = the volume of air theoretically necessary, and  $L$  = the excess of air admitted,  $L_0 = R - L - G + c - d$ . This equation is applicable to moist flue gases if the volume of the water-vapor in them is taken into consideration. On the customary assumption that  $L = R - G$ , the ratio  $\frac{L}{L_0}$  may have only half its proper value.

If  $E$  = the percentage of air in excess of that theoretically of combustion,  $X$  = volume of oxygen theoretically necessary,  $x$  = the excess of oxygen in the product required for the combustion, and  $R$  = the volume of products of combustion,  $E = \frac{100 Rx}{X}$ . Fischer's ratio,

$\frac{21}{21 - 79 \frac{o}{n}}$  : 1 (where  $o$  = per cent of oxygen and  $n$  =

per cent of nitrogen in the products of combustion), is applicable to coal, coke and illuminating gas, but not to producer gas and other fuels containing a considerable percentage of nitrogen. Furthermore, use of the percentage of nitrogen in the products of combustion as a basis for calculating the excess of air present is unsatisfactory, since a variation of 10 per cent in the latter causes a variation of only 0.1 per cent in the nitrogen, but a variation of 8 per cent in the free oxygen.

"The Estimation of Tin in High-Grade Wolframite and the Use of Lead as a Reducing Agent in Pearce's Assay" was the subject of a paper read by A. R. POWELL at the June meeting of the London section of The Society of Chemical Industry.<sup>1</sup> Four methods were discussed for the quantitative separation of small quantities of tin from rich tungsten ores, two of which were devised by the author. In the older methods the ore was boiled with aqua regia, the insoluble stannic and tungstic oxides filtered and extracted with ammonia, the residual stannic oxide being fused with sodium peroxide and the assay continued in the usual way; or the ore may be fused with cyanide and the ferro-stannic residue dissolved in hydrochloric acid and the solution reduced and titrated.

The author's first method consists of fusing the ore with sodium peroxide and making the melt up to a

known volume with water. An aliquot portion is filtered off and the tin separated either by boiling the solution with ammonium nitrate, or the alkaline solution is acidified with tartaric acid together with a slight amount of hydrochloric acid, then the tin is precipitated with hydrogen sulphide.

In the second method, the ore is fused in sodium acid sulphate and the melt boiled with tartaric acid, which dissolves everything except tin oxide and gangue; then the insoluble residue is filtered and fused in sodium peroxide. Copper, bismuth and molybdenum are removed by extracting the ore with nitric acid.

The author has found that stannic chloride solutions can be reduced satisfactorily by lead or zinc-lead instead of iron, it being unnecessary to remove the lead in order to titrate; moreover, the solution is colorless. This method is a rapid one, since sixteen to twenty assays can be made by it per hour.

**Lignin from Sulphite Waste Liquors.**—An article in *Svensk Pappers-Tidning* by MR. R. W. STREHLENER gives an account of a process for the precipitation of the dissolved colloidal lignin. As there is practically a ton of organic matter carried away in the waste liquor to every ton of dry pulp made, five-eighths of which are lignin, one-fourth other carbohydrates, and the remainder resins and organic acids, the importance of recovering and utilization of this material is obvious. Klason has determined the molecular weight for lignin to be about 6000, which would indicate an approximate formula of  $(C_6H_7O_2)_n$ . The lignin is in solution in the waste liquor as a calcium ligno-sulphonite salt. Strehlener finds that at the critical temperature, at which  $SO_2$  is given off by decomposition, oxygen rapidly acts on the sulphite ions giving sulphate ions, which form lime salts insoluble in the presence of excess  $SO_2$  and thus break up the complex ligno-compounds. As the reaction,  $3SO_2 \rightarrow 2SO_3 + S$ , takes place under the conditions of temperature and pressure used, air is not essential for the decomposition (phenomenon called "black cook in papermaking") but a coarser precipitate is obtained with air oxidation, which is more easily filtered and dried. Strehlener is using the dried filter cake for fuel at Gota, Norway. As coal is cheaper in America and labor more expensive than in Norway, it is doubtful whether lignin would be an economical fuel.

**Discoloration of White Paint.**—At a recent meeting of the Society of Chemical Industry at Birmingham, Eng.,<sup>1</sup> Dr. D. F. Twiss discussed the yellowing of white paints. Lead, zinc and barium pigments were found to be equally susceptible and the evidence indicated that the source of discoloration was not in the pigment but in the oil. When a little of the oil was separated from the paint and absorbed into paper free from mineral impurities, the dried film, on being kept in a warm place, was found to develop gradually a marked yellowish brown color. Bleached films were immediately disclosed by keeping in a warm place unexposed to actinic action and the discoloration and bleaching processes were repeated many times in succession, the tendency to discolor undergoing but slight diminution. Artists have found that walnut and poppy seed oils have less tendency to turn yellow, but for commercial work, linseed is the oil par excellence.

## Book Reviews

**EDIBLE FATS AND OILS.** By C. Ainsworth Mitchell, B. A., F. I. C. Pages, 159. Price, \$2.00. New York and London: Longman, Green & Co.

This little volume is one of the Monographs on Industrial Chemistry, edited by Sir Edward Thorpe, C.B., LL.D., F. R. S.

As stated in the preface, it gives a "concise outline of the chemical composition and properties of the more important oils and fats, together with a description of the methods of extracting them from the crude material and of purifying them for food purposes."

Although the author has worked with the end in view of giving principles rather than working details of the various analytical processes mentioned, he has succeeded in a wonderfully small space in giving very full information regarding modern methods of oil and fat investigation, while the tables of constants and thirty-three pages of bibliography make it a valuable work of reference to the specialists.

The portion of the work dealing with manufacturing processes is little more than a sketch and is in no way to be considered as a guide to their application, but rather a source of general information.

The chapters on hydrogenation and margarine manufacture considered as short general outlines are particularly good, while a very complete index adds greatly to the value of the volume as a concise book of reference.

**PETROLEUM, ASPHALT AND NATURAL GAS.** By Roy Cross. Pages (5 x 7½), 212. Price \$2.00. Kansas City, Missouri: Kansas City Testing Laboratory.

This little leather-bound volume is Bulletin No. 14 of the Kansas Testing Laboratory. It is very practical and well-nigh indispensable to petroleum and gas chemists, having statistics, physical, chemical and pneumatic tables and many illuminating features. The table on page 62-63 on "Horizontal Cylindrical Tank" segments should have had some explanatory remarks—and should have included spherical lumps and steam coil segments, besides referring to the published actual calibrations of tank cars by name and number. Twenty blank pages are reserved for notes facilitating additions to the volume.

**THE ALKALI INDUSTRY.** By J. R. Partington. Pages (demy octavo) 304. Price, \$1.80. London: Baillière, Tindall & Cox.

The title of this book is not sufficiently inclusive since the author devotes over 60 per cent of its space to sulphuric and nitric acids, chlorine and iodine. The treatment of the salt industry, soda processes, electrolytic processes, ammonia, potash and magnesia is less elaborate than desirable, being too extensive for the general reader and of little practical value in training an alkali chemist. The many modern electrolytic cells are not even mentioned in the eight-page chapter on "Electrolytic Processes." In the contact process for the manufacture of sulphuric acid and the oxidation of ammonia to nitric acid, the reader will find an introduction to the great recent developments in this branch, but of course no complete accounts will be available under present international conditions.

MR. JOHN C. MERRILL is the successor to the firm of Sulliger and Merrill, located at 1400 Hibernian Building, Los Angeles, California.

PROFESSOR JULIUS STIEGLITZ, chairman of the department of chemistry at the University of Chicago, has been appointed special expert in the United States Public Health Service of the Treasury Department. This will not involve his work at the university. The government assigns him two assistants, who will be in the employ of the Public Health Service and will carry out their work in Kent Chemical Laboratory under Professor Stieglitz's direction.

MR. SAMUEL WIERMAN has resigned his position as chief chemist at the Citrus By-Products Company, Corona, California, to accept the position of chemist-in-charge of the Chemical and Agricultural Department of the Société Financière des Caoutchoucs of Antwerp, Belgium, and London, England. The scientific departments of the Société are located in the Federated Malay States, convenient to their rubber plantations in the Malay States, Sumatra and Java.

## Current Market Reports

### Non-Ferrous Metal Market

**Wednesday, August 7.**—Prices have remained stationary during the past two weeks. Government price-fixing seems to have served as an antidote for speculating.

**Aluminum.**—The government prices on ingots are 33c. a pound f.o.b. plant in 50-ton lots, 33.1c. down to 15-ton lots and 33.2c. in lots down to 1 ton, which prices will be effective until September 1. Prices for small lots vary from 40c. to 45c.; sheet aluminum, 18 ga., and heavier, 42c.; powdered aluminum, \$0.65 to \$3.00 per pound, according to mesh.

**Antimony.**—The demand is very weak and spot duty paid has fallen in price, 13c. to 13½c.

**Chrome.**—Large quantities of high-grade material have been sold at a premium, 50 per cent ore bringing \$1.70 per unit.

**Copper.**—Government price fixed at 26c. for carload lots and 27.3c. for smaller quantities is expected to be changed on August 15. A conference is being held between the producers and the War Industries Board, and it is probable that no official increase in price will be allowed without considerable delay and presidential sanction.

|                              |     |        |          |
|------------------------------|-----|--------|----------|
| Copper sheets, hot rolled... | lb. | \$0.36 | — \$0.37 |
| Copper sheets, cold rolled   | lb. | .37    | .38      |
| Copper bottoms.....          | lb. | .44    | .43      |

| Seamless brass tubing.....   | lb. | .37    | .39      |
| Bronze (gold) powder.....    | lb. | 1.00   | 1.75     |

**Lead.**—Demand strong with supplies scarce. War consumption has been exceptionally heavy. A limited quantity of prompt lead is quoted at 8½c. to 8¾c. September and October deliveries prices in New York, 8.05c. per lb.; East St. Louis, 7.75c. in 60,000-lb. lots; full sheet lead, 10c.; cut sheets, 10½c.

**Manganese.**—Prices remain at \$1.35 per unit basis.

**Molybdenum.**—Domestic demand still lacking. The price is nominally \$1.00 per unit of 90 per cent MoS<sub>2</sub>.

**Spelter.**—Spot delivery in New York is quoted at 8.5c. to 8.6c. for prime Western. East St. Louis, all positions to the end of the year range between 8.1c. and 8.2c. Sheet zinc is 15c. and zinc dust, 16c. to 20c. per pound in 1600-lb. barrels.

**Tin.**—Owing to river floods in China, transportation of tin there has been interrupted, with consequent advance in Singapore prices to 98½c. f.o.b. London. Open market in New York dull with prices varying between 92c. and \$1.00. Babbitt metal varies between \$1.10 and 70c. per pound. Solder 50-50, 73c.

## Personal

MR. STUART B. MARSHALL, formerly manager of the American Manganese Manufacturing Co., Dunbar, Pa., and until recently general superintendent of the Aluminum Company of America's properties and business in North Carolina, at Badin, is now located at Roanoke, Va., as consulting engineering chemist and metallurgist for coal and ore lands, blast furnaces, manganese pyrites, antimony, lead and zinc deposits, ferromanganese and spiegel operations, minerals, etc.

**Tungsten:**—The British government has attempted to steady the tungsten industry by guaranteeing a price of 60 shillings a unit for the duration of the war and six months thereafter. The highest grade material, containing no tin, no copper and low manganese and over 70 per cent Wo., is selling at \$25.50 per unit. Lower grades vary between \$20.00 and \$24.00.

#### OTHER METALS

|              |        |        |         |

### The Iron and Steel Market

Further regulations have been made by the War Industries Board for the distribution of steel, in addition to those summarized in last report. Jobbers, who were accorded a B-4 preference for the replacement of material, month by month, that had been shipped the previous month on priorities and preferences, are given special treatment as to mill shipments to them for August, this taking the place of the regular procedure, which becomes effective for September. For August the mills are permitted to ship jobbers an amount of material equal to the monthly average shipped during the first half of the year. In some finished steel branches, like wire products and pipe, the mills can do fairly well under these regulations, but in sheets, merchant bars and some other products it is represented that by the time higher preferences are provided for there will be little if any material left to take a Class B-4 rating.

What is called "automatic priority" is provided for many descriptions of steel, each use prescribed being given its particular priority, as AA-2, A-3, B-6, etc. The buyer, when placing his order, makes a formal endorsement on it, certifying the use to which the material is to be put and naming the degree of priority that is accorded by the regulations. Commercial buyers must make affidavit; representatives of the Government need not. While this arrangement as to "automatic priority" seems like a radical step, in essence it is but a natural development, in that the Priorities Division as it gained experience had developed certain rules for its guidance in determining the degree of priority, if any, and when the rules became sufficiently stabilized procedure under them was simply handed over to the buyers.

These priorities, in the present complicated form, must be regarded purely as expedient to meet an undesirable condition, it is hoped, a temporary situation. After the priorities come the preferences, and then Class D material, for purposes that are given no recognition. Obviously there is no occasion for a priority order for a given description of material if there is a supply of it left for the preference list, and obviously it is highly undesirable that there should be none of such material for the preference list, not to mention Class D consumers. The priority order does not alter the conduct of a mill if it can make the desired delivery without. It is only when the delivery desired by the buyer cannot be made otherwise that the priority order operates. Hence if there is enough steel for all the priorities they disappear as a governing factor. Eventually, it is hoped, priorities will become purely a matter of form and the desired deliveries will be made without their influence being exerted. The War Industries Board reserves the right to modify the priorities produced by the automatic system, in any particular case, and of course many uses are not covered by the list and the steel for such uses will still be given individual priority orders by the board.

#### STEEL REQUIREMENTS

While in July the War Industries Board made the statement that the finished steel requirements for the second

half of the year amounted to between 20,000,000 and 21,000,000 net tons, while output had never exceeded 16,500,000 net tons, in conferring subsequently with the Fuel Administration, as to supplies of bituminous coal for the steel industry, it stated that the requirements were 22,000,000 tons, so that it evidently had not given up hope of the industry being able to produce more than 16,500,000 tons. This hope is well founded. The rate of production in May and June was nearly if not quite 3,000,000 tons, while July has done almost as well, despite the season of the year, and gains on 3,000,000 tons a month are therefore to be expected for the fall months, with possibilities therefore of 18,000,000 to 19,000,000 tons for the half year.

Some details have been furnished the steel makers as to how the total for the half year is made up, and the statement has also been made that the requirements for the first half of 1919 promise to run 20,000,000 tons or more. The steel industry is disposed to take the schedule as correct, although there remains some doubt whether the various activities will really be able to operate at expected rates and use the steel within the periods prescribed.

All estimates are necessarily rough as in all activities the greatest pressure is being applied, and this pressure will naturally be more successful in producing results at some points than at others. No activity is being curbed to suit the pace of another activity. In shipbuilding there is the shipment of the steel, the fabricating at detached plants, the work on the shipways and the work in the fitting out basins, with a thousand things to be supplied the ship before it is completed. Theoretically, the Director of Shipbuilding would apply pressure where most needed but his conduct to date has been that of applying pressure everywhere, showing no favoritism. Boilers are the crying need when he talks to boiler makers, the driving of rivets when he talks to the shipyard workers, and so all along the line.

#### WAR ACTIVITIES

There have been heavy lettings of shell contracts, involving a material increase in the rate of shell steel consumption. If the production of shell steel has not already exceeded a rate of 500,000 net tons a month it probably will do so in the near future. Since the first of the year there has been a large increase in the forging capacity for large shells, particularly 6-inch and larger, in which there was formerly a marked deficiency. With the demand running more largely to steel for large shells the burden upon the steel industry in the matter of rolling the steel is decreased, while the amount of steel subtracted from the supply to finishing departments in general is increased.

The plate allotment for shipbuilding in the United States is 50,000 net tons a week, or about 2,600,000 tons a year. Estimated production, including universal mill plates, is about 6,000,000 tons a year, nearly double the actual output of 1916, which represented approximately the existing capacity at the time. Further increases in plate production are in sight, through new construction, and by the end of the year there may be an increase of as much as 50,000 or 75,000 tons a month over the present rate. This heavy production of plates operates as does the heavy production of shell steel, to take raw steel out of the general situation and force finishing departments making less essential products, or products that are called for by war activities in smaller proportions, to operate at far below their capacity. Taking the rod mills, pipe mills, sheet mills and merchant bar mills as a whole, their operation is not over about 65 per cent of capacity.

#### NEW CONSTRUCTION CONSIDERED

This situation, coupled with the fact that the byproduct coking capacity has been increasing steadily and is marked for indefinite increase in future, as even in the past three months new plants have been projected, some with financial assistance by the Government, has led to an investigation of new construction as a means of providing more steel. It is readily seen that a fully integrated operation need not be constructed. There would probably be enough coke making capacity, if supplied with coal, also enough iron ore, at least for a time, and there would be enough finishing capacity,

if the present output of the finishing departments that are being operated at less than capacity is not sufficient for the war requirements, direct and indirect. Indications pointed strongly to the fact that additional blast furnaces and open-hearth furnaces, with perhaps an occasional blooming mill and slabbing mill, would increase the steel industry's capacity effective for war work. At the same time, viewed from the standpoint of the normal requirements of peace times, there would be left an excess of pig iron and steel making capacity. Accordingly the matter has been canvassed of the Government extending financial assistance in connection with the new construction, against which heavy amortization charges would have to be laid in view of the conditions. At the same time the influence of the War Industries Board would have to be invoked to provide the necessary man power and materials. To an extent yet to be determined, so far as is now known, this would be to the detriment of other war activities. Formal announcement of a decision on this matter may or may not be made in the near future.

#### STEEL PRICES

The very large profits and earnings being reported by steel companies indicate very clearly that there is no prospect of the War Industries Board advancing prices at any time. There may be some rearrangements of schedules, but no general advance is in prospect, and there may easily be horizontal reductions. The argument that some producers make much smaller profits than large producers has not been supported by citation of an adequate number of cases. The arguments are usually confined to generalities. Nor does the argument that wage advances increase cost of production and increased cost of production should be followed by advanced prices follow a logical sequence. The wage advances have as a rule been based upon the large earnings the employers were already enjoying.

#### Chemical Market

**HEAVY CHEMICALS:**—The market in general has not shown very great activity. Saccharine, both grades, has been on strong call with consequent appreciation in prices, but with regard to caustic there has been some uncertainty of just what might occur in view of the new Government regulations. Some discussion was raised also as to what might constitute a reasonable profit to dealers in sulphuric acid, but this has been dropped and business is continuing to be done at whatever the buyer is willing to pay.

**Glycerine:**—No definite confirmation has been received locally of the press dispatches from Washington concerning the so-called fixing of glycerine prices. Nevertheless, the trade is of the opinion that the matter has been definitely decided and that only an official announcement remains to be made. The prices are stated to be 60c., August-September; 58c. for October-November and 56c. for December. This of course is for dynamite glycerine. As we have before mentioned, the matter of a fixed price for dynamite glycerine was only a matter of time, although the War Industries Board has stated that they did not see the necessity of such a fixed price at the moment. However, the Food Administration thought otherwise and as it is known that the allied governments are about to purchase large quantities on this market the price fixing arrangement has at last materialized. There is practically no spot market at the present, although refiners express a willingness to sell at 60c. C.P. holds at 62c. The crude situation is much weaker and refiners claim purchases at 40c. loose for soap lye and 44c. for saponification.

**Metabisulphite of Potash:**—Prices asked for this material show a slightly advanced level due to the government taking the majority of the supplies available and very little being offered on the open market. Some lots are to be had but they are said to be small. Crystal material is held at from 1.20 to 1.40 with the powdered at from 1.10 to 1.20.

**Metabisulphite of Soda:**—This item has not been very active and prices quoted continue at about 30c. Large quantities, however, could be purchased at a lower figure, possibly 25c. in ton lots.

**Sodium Sulphide:**—Actual holders of spot lots of material are very hard to locate with the exception of one lot for immediate delivery at 8c. Prices are being quoted f.o.b. factory at 6.50, although a single sale was lately reported of material for September shipment at 2.00 advance over this figure.

**Carbon Tetrachloride:**—For a long time the Government requirements have been more than they were receiving, but leaving then but a small amount for the open market. It is understood that now not a pound can be distributed to consumers without first submitting questionnaire to Washington. Only one or two drums are still in second hands, but these cannot be bought for less than 28c. at the least.

**Caustic Soda:**—In some directions sellers are asking 4.25 but demand is very quiet and in some instances sales have resulted at below the market, in one particular a carload at 3.90 ex store for standard material.

**Bichromate of Soda:**—A rather unusual lull prevails in the situation, and nominally the market remains at 26c. Some interests are of the opinion that something is going to happen. Tanneries would no doubt welcome a fixed price such as the Government has established on hides but a fixed price on the chemical would necessarily mean a fixed price on chrome ore and a regulated source of supply of this raw material. Developments may be expected in other directions it is reported as an official of the Government is known to have been gathering data relative to numbers of producers, quantities produced and so forth, but nothing has yet been heard from Washington definitely.

**COAL TAR PRODUCTS:**—Not very great activity has been evident and all the coal tar items have held rather steady with regard to price excepting particularly saccharine, which continues to make firm progress, with a tendency toward a resuming of the former relations between the two grades.

**Phthalic Anhydride:**—Inquiries have been rather strong for this material and the supplies which have been fast lowering are said to be about exhausted. It is now practically impossible to place an order for prompt shipment and the best that can be done is October. Prices, therefore, are showing a firmness with quotations from 4.75 to 5.00 f.o.b. works.

**Saccharine:**—The general askings where there are actual holdings of material are at 36.00 for the soluble, to which level the askings for insoluble also advanced with a tendency to again assume a precedence, as at this writing it is understood that this latter grade is being quoted in several directions at 37.00 and 38.00. Some of the holders of soluble have been holding back their stocks for better prices; but undoubtedly now, with the preference being shown for insoluble, they will let material out. Certain holdings available for export, having affidavit attached, are at 45.00.

**Coumarin:**—Manufacturers are behind in their shipments and dealers having contracts are therefore unable yet to accept orders for immediate delivery. It is understood that manufacturers are not able even to state when they will be in a position to supply. Inquiry is strong and there are buyers willing to pay 32.50. Large inquiries for export material are also extant.

**Paranitrophenol:**—Supplies are said to be not very large and prices are firm at from 1.65 to 1.75 with good inquiry. From some directions quotations are made at from 1.60 to 1.70 for the needle crystals, depending upon quality and quantity.

**Orthonitrophenol:**—In general stocks are rather short although certain directions are understood to be preparing to take care of large orders. Very little spot material is available and most directions are quoting for future deliveries; that is, September first and after. Prices continue firm at from 1.50 to 1.60 f.o.b. works.

**Guaiacol Liquid:**—The price of 15.00 per pound holds firm as asked by some of the largest factors in its production. Although it is said that present supplies are about sufficient to take care of the present demand, this latter is

growing and preparations for meeting it by enlarged manufacturing facilities and shipments on the new scale are expected to be made shortly.

**Para-amidophenol.**—Prices quoted on this item continue firm at from 4.00 to 4.50 for the base and from 4.25 to 5.00 for the H.C.L., depending upon quantity.

**Orthoamidophenol.**—Prices remain unchanged as the general askings by the few holders are at 6.50 on orders for reasonable amounts, although on attractive business this would undoubtedly be shaded.

## General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET, AUG. 9, 1918

|                                                |         |               |        |

| Sodium bisulphate, powd.                        | lb.     | .25     | .25½  |
| Sodium chlorate                                 | lb.     | .37     | .42   |
| Sodium cyanide                                  | lb.     | .17     | .18   |
| Sodium fluoride, commercial                     | lb.     | 2.50    | 3.60  |
| Sodium hyposulphite                             | lb.     | 4.12    | 5.00  |
| Sodium molybdate, per lb. of Mo.                | 100 lb. | .28     | .30   |
| Sodium nitrate, 95 per cent                     | lb.     | .35     | .45   |
| Sodium nitrate                                  | lb.     | .04     | .04½  |
| Sodium peroxide                                 | lb.     | .51½    | .53½  |
| Sodium persulphate, yellow                      | lb.     | .02½    | .03½  |
| Sodium silicate, liquid (60 deg.)               | lb.     | 8.00    |       |
| Sodium sulphide, 30 per cent, crystals          | 100 lb. | .06     | .07   |
| Sodium sulphide, 60 per cent, fused             | 100 lb. | .25     | .26   |
| Sodium sulphite                                 | lb.     | .15     | .16   |
| Sodium sulphate, 98 per cent, drums             | 100 lb. | 4.05    | 3.85  |
| Sulphur, flowers, sublimed                      | ton     | 65.00   | 70.00 |
| Sulphur, crude                                  | lb.     | .18     | .20   |
| Sulphur, 90 per cent                            | lb.     | 1.00    | .29   |
| Tin bichloride, 50 deg.                         | lb.     | 1.28    | 1.10  |
| Tin oxide                                       | lb.     | 1.00    | 1.10  |
| Zinc carbonate                                  | lb.     | .15     | .16   |
| Zinc chloride                                   | lb.     | .15     | .15½  |
| Zinc cyanide                                    | lb.     | Nominal |       |
| Zinc dust, 35 mesh                              | lb.     | .13½    | .14   |
| Zinc oxide, American process XX                 | lb.     | .04½    | .06½  |
| Zinc sulphate                                   | lb.     | .04½    | .06½  |

## Coal Tar Products (Crude)

|                                        |      |               |       |
|----------------------------------------|------|---------------|-------|
| Benzol, pure, water white              | gal. | .23           | .26   |
| Benzol, 90 per cent                    | gal. | .25           |       |
| Toluol, in tank cars                   | gal. | (Fixed Price) | 1.50  |
| Toluol, for non-military use, in drums | gal. | (Fixed Price) | 1.55  |
| Xylo, pure, water white                | gal. | .18           | .20   |
| Solvent naphtha, water white           | gal. | .18           | .28   |
| Solvent naphtha, crude, heavy          | gal. | .12           | .15   |
| Cresote oil, 25 per cent               | gal. | .14           | .55   |
| Dip oil, 20 per cent                   | gal. | .30           | .32   |
| Pitch, various grades                  | ton  | 8.00          | 20.00 |
| Carbolic acid, crude, 95-97 per cent   | lb.  | .05           | 1.10  |
| Carbolic acid, crude, 50 per cent      | lb.  | .35           | .38   |
| Carbolic acid, crude, 25 per cent      | lb.  | .18           | .20   |
| Cresol, U. S. P.                       | lb.  | .18           | .20   |

## Intermediates, Etc.

|                               |     |         |       |
|-------------------------------|-----|---------|-------|
| Alpha naphthol, crude         | lb. | 1.00    | 1.10  |
| Alpha naphthol, distilled     | lb. | 1.00    | 1.10  |
| Alpha naphthylamine           | lb. | .60     | .65   |
| Aniline oil, drums extra      | lb. | .28     | .30   |
| Aniline salts                 | lb. | .40     | .45   |
| Anthracene, 80 per cent       | lb. | Nominal |       |
| Benzaldehyde (f.i.c.)         | lb. | 3.60    | 4.00  |
| Benzidine, base               | lb. | 1.75    | 1.85  |
| Benzidine, sulphate           | lb. | 4.00    | 1.50  |
| Benzonic acid, U. S. P.       | lb. | 3.00    | 3.25  |
| Benzoate of Soda, U. S. P.    | lb. | 2.90    | 3.00  |
| Benzyl chloride               | lb. | 2.45    | 2.50  |
| Beta naphthol benzoate        | lb. | 10.00   | 12.00 |
| Beta naphthol, sublimed       | lb. | .85     | .90   |
| Beta naphthylamine, sublimed  | lb. | 2.65    |       |
| Dichlor benzene               | lb. | .65     | .70   |
| Diethylaniline                | lb. | 4.50    | 5.00  |
| Dinitrobenzol                 | lb. | .36     | .38   |
| Dinitrochlorobenzol           | lb. | .40     | .45   |
| Dinitronaphthalene            | lb. | .50     | .55   |
| Dinitrotoluol                 | lb. | .65     | .75   |
| Dinitrophenol                 | lb. | .55     | .60   |
| Dimethylaniline               | lb. | .70     | .78   |
| Diphenylamine                 | lb. | 1.00    | 1.10  |
| H-anil                        | lb. | 3.00    | 3.25  |
| Metaphenylenediamine          | lb. | 1.85    | 2.05  |
| Monochlorobenzol              | lb. | .65     | .70   |
| Naphthalene, flake            | lb. | .09     | .09½  |
| Naphthalene, balls            | lb. | .10½    | .10½  |
| Naphthionic acid, crude       | lb. | 1.20    | 1.30½ |
| Naphthylamine, sulphonic acid | lb. | 1.00    | 1.10  |
| Nitro naphthalene             | lb. | .45     | .50   |
| Nitro toluol                  | lb. | .55     | .60   |
| Ortho-amidophenol             | lb. | .15     | .18   |
| Ortho-dichlorobenzol          | lb. | .95     | 1.10  |
| Ortho-toluidine               | lb. | .75     | .85   |
| Ortho-nitro-toluol            | lb. | 4.00    | 4.50  |
| Para-amidophenol, base        | lb. | 4.25    | 5.00  |
| Para-amidophenol H. Ch.       | lb. | .15     | .20   |
| Para-dichlorobenzol           | lb. | 1.65    | 1.75  |
| Paranitraniline               | lb. | 1.50    | 1.60  |
| Para-nitro-toluol             | lb. | 3.00    | 3.5   |
| Para-phenylenediamine (base)  | lb. | 2.00    | 2.25  |
| Phthalic acid anhydride       | lb. | 4.00    | 4.50  |
| Phenol, U. S. P.              | lb. | 5.50    | 7.00  |
| Resorcin, technical           | lb. | 8.00    | 9.00  |
| Resorcin, pure                | lb. | .90     | 1.10  |
| Sulphuric acid                | lb. | 1.00    | 2.00  |
| Sulphanilic acid, crude       | lb. | .30     | .32   |
| Tolidin                       | lb. | 2.50    | 3.00  |
| Tolidine-mixture              | lb. | .85     | .90   |

## Petroleum Oils

## Crude (at the Wells)

## Lubricants

|                                                  |      |     |     |
|--------------------------------------------------|------|-----|-----|
| Black, reduced, 29 gravity, 25-30 cold test..... | gal. | .23 | —   |
| Cylinder, light.....                             | gal. | .40 | .42 |
| Cylinder, dark.....                              | gal. | .39 | —   |
| Paraffine, high viscosity.....                   | gal. | .40 | .41 |
| Paraffine, 903 sp. gr.....                       | gal. | .36 | .38 |
| Paraffine, 885 sp. gr.....                       | gal. | .25 | .27 |

## Flotation Oils

(Prices at New York unless otherwise stated)

|                                                                          |      |     |     |
|--------------------------------------------------------------------------|------|-----|-----|
| Pine oil, crude, f. o. b. Florida.....                                   | gal. | .44 | —   |
| Pine oil, steam-distilled, sp. gr. 0.925-0.940.....                      | gal. | .58 | .60 |
| Pine oil, destructively distilled.....                                   | gal. | .35 | —   |
| Pine-tar oil, sp. gr., 1.02-1.035.....                                   | gal. | .42 | —   |
| Pine-tar oil, double refined, sp. gr. 0.965-0.990.....                   | gal. | .42 | —   |
| Pine-tar oil, ref., light, sp. gr. 0.950, tank cars, f. o. b. works..... | gal. | .37 | —   |
| Pine-tar oil, ref., heavy, sp. gr. 1.025, tank cars, f. o. b. works..... | gal. | .28 | —   |
| Pine-tar oil, ref., thin, sp. gr. 1.060-1.080.....                       | gal. | .45 | —   |
| Turpentine, crude, sp. gr. 0.870-0.900.....                              | gal. | .23 | —   |
| Hardwood oil, f. o. b. Michigan, sp. gr. 0.960-0.990.....                | gal. | .23 | —   |
| Hardwood oil, f. o. b. Michigan, sp. gr. 1.06-1.08.....                  | gal. | .31 | —   |
| Wood creosote, ref. f. o. b. Florida.....                                | gal. | .31 | —   |

## Naval Stores

|                                               |          |       |       |
|-----------------------------------------------|----------|-------|-------|
| Rosin A-F barrel.....                         | 280 lb.  | 11.20 | 11.30 |
| Rosin F-I.....                                | 280 lb.  | 11.45 | 11.70 |
| Rosin K-N.....                                | 280 lb.  | 12.50 | 12.70 |
| Rosin W-G-W.....                              | 280 lb.  | 13.00 | 13.10 |
| Spirits of turpentine.....                    | gal.     | .61   | .62   |
| Wood turpentine, steam distilled.....         | gal.     | .63   | —     |
| Wood turpentine, destructively distilled..... | gal.     | .56   | —     |
| Pitch.....                                    | bbl. 200 | 12.50 | —     |
| Tar, kiln dried.....                          | 280 lb.  | 13.50 | —     |
| Retort tar.....                               | gal.     | .62   | —     |
| Rosin oil, first run.....                     | gal.     | .62   | —     |
| Second run.....                               | gal.     | .66   | —     |
| Fourth run.....                               | gal.     | .73   | —     |

## Vegetable Oils

|                               |      |      |      |
|-------------------------------|------|------|------|
| Castor oil.....               | lb.  | .281 | .30  |
| China wood oil.....           | lb.  | .30  | .32  |
| Cocanut oil.....              | lb.  | .18  | .18  |
| Corn oil.....                 | lb.  | .20  | .22  |
| Cottonseed oil, crude.....    | gal. | 1.88 | 1.90 |
| Lined oil, raw, cars.....     | gal. | 1.36 | 1.37 |
| Peanut oil, crude.....        | lb.  | .16  | —    |
| Soya bean oil, Manchuria..... | lb.  | .16  | —    |

## Miscellaneous Materials

|                                          |         |       |       |
|------------------------------------------|---------|-------|-------|
| Barytes, floated, white, foreign.....    | ton     | 38.00 | 42.00 |
| Barytes, floated, white, domestic.....   | ton     | 25.00 | 36.00 |
| Brewers, white, pure.....                | lb.     | .42   | .43   |
| Casoin.....                              | lb.     | .173  | —     |
| Ceylon graphite.....                     | lb.     | .071  | —     |
| Chalk, light, precipitated, English..... | ton     | 20.00 | 25.00 |
| China clay, imported, lump.....          | ton     | 15.00 | 22.50 |
| China clay, domestic, lump.....          | ton     | 8.00  | 12.00 |
| FelDSPar.....                            | ton     | 60.00 | —     |
| Fluorspar, gravel, f. o. b. mines.....   | ton     | 90.00 | —     |
| Fluorspar, washed, powdered.....         | 100 lb. | 1.50  | 2.00  |
| Fuller's earth, powdered.....            | 100 lb. | 1.50  | —     |
| Mexican graphite.....                    | ton     | 75.00 | —     |
| Madagascar graphite.....                 | lb.     | .10   | .15   |
| Ookerite, crude.....                     | lb.     | .35   | .36   |
| Ookerite, American, refined, white.....  | lb.     | .85   | .90   |
| Red lead, dry, carloads.....             | ton     | 1.0   | 1.14  |
| Sopstone.....                            | ton     | 15.00 | 25.00 |
| Talc, American, white.....               | ton     | 20.00 | 40.00 |
| White lead, dry.....                     | lb.     | .094  | .104  |

## Glues

|                                 |      |      |      |
|---------------------------------|------|------|------|
| Extra white.....                | lb.  | .36  | .45  |
| Cabinet.....                    | lb.  | .31  | .40  |
| Brown foot stock.....           | lb.  | .28  | .22  |
| Fish glue, 50-gal. barrels..... | gal. | 1.00 | 1.80 |

## Refractories, Etc.

(F. O. B. Works)

|                                       |          |        |        |
|---------------------------------------|----------|--------|--------|
| Chrome brick.....                     | net ton  | 175.00 | —      |
| Chrome cement.....                    | net ton  | 75.00  | —      |
| Clay brick, 1st quality fireclay..... | per 1000 | 50.00  | 55.00  |
| Clay brick, second quality.....       | per 1000 | 35.00  | 40.00  |
| Magnesite, raw.....                   | ton      | 50.00  | 65.00  |
| Magnesite, calcined, powdered.....    | net ton  | 50.00  | 60.00  |
| Magnesite, dead burned.....           | net ton  | 110.00 | 125.00 |
| Magnesia brick, 9x4 1/2x2 1/2.....    | per 1000 | 50.00  | 60.00  |
| Silica brick.....                     | net ton  | 110.00 | 125.00 |

## Ferrous Alloys

|                                                                            |     |        |        |
|----------------------------------------------------------------------------|-----|--------|--------|
| Ferrocobaltum, 15-18 per cent, carloads, f. o. b. Niagara Falls, N. Y..... | ton | 200.00 | 250.00 |
| Ferrocobaltum.....                                                         | lb. | 15.00  | 30.00  |
| Ferrocobaltum, per lb. of Cr.....                                          | lb. | 250.00 | —      |
| Ferromanganese, domestic, 70 per cent basic.....                           | ton | 325.00 | —      |
| Ferromanganese, English.....                                               | ton | 75.00  | —      |
| Spiegel.....                                                               | ton | 4.00   | 4.50   |
| Ferrosilicon, 75 per cent, f. o. b. Mo.....                                | lb. | 180.00 | 190.00 |
| Ferrosilicon, 75 per cent, f. o. b. N. Y.....                              | ton | 160.00 | 170.00 |
| Ferrosilicon, 50 per cent, carloads, del., Pittsburgh.....                 | ton | 2.35   | 2.40   |
| Ferrotungsten, 75-85 per cent, f. o. b. Pittsburgh.....                    | lb. | 7.50   | —      |
| Ferroumium, f. o. b. works, per lb. of U.....                              | lb. | —      | —      |
| Ferrovandium, f. o. b. works.....                                          | lb. | —      | —      |

## Ores and Semi-finished Products

|                                                                |      |       |        |
|----------------------------------------------------------------|------|-------|--------|
| Antimony ore, per unit.....                                    | ton  | 1.50  | 1.55   |
| Chromite ore, 45 per cent minimum, f. o. b. Cal. per unit..... | ton  | 1.20  | —      |
| Chromite ore, 45 per cent and over, New York, per unit.....    | ton  | 1.20  | —      |
| Manganese ore, 48 per cent and over, per unit.....             | ton  | 80.00 | 100.00 |
| Manganese ore, chemical.....                                   | lb.  | 1.25  | —      |
| Molybdenite, per lb. of MoS <sub>2</sub> .....                 | ton  | 24.00 | —      |
| Tungsten, Scheelite, per unit of WO <sub>3</sub> .....         | ton  | 24.00 | —      |
| Tungsten, Wolframite, per unit of WO <sub>3</sub> .....        | lb.  | 3.25  | 3.60   |
| Uranium oxide, 96%.....                                        | lb.  | 10.50 | —      |
| Vanadium pentoxide, 99%.....                                   | unit | .17   | .17    |
| Pyrites, foreign.....                                          | unit | .28   | .304   |
| Pyrites, domestic.....                                         | unit | .28   | —      |

## Financial, Construction and Manufacturers' News

### Construction and Operation

#### Alabama

**FLORENCE**.—The city will enlarge its filtration plant. Estimated cost, \$175,000. Address the Mayor.

#### Arkansas

**BIERNE**.—J. A. Schofield, Warren, Pa., is interested in a plan to build a factory for the manufacture of wood alcohol and other chemicals.

#### California

**STOCKTON**.—The Wagner Leather Co. will rebuild its tannery recently destroyed by fire. The new building will be four story, of brick construction.

#### Connecticut

**HARTFORD**.—Henry Souther Engineering Co., 11 Laurel St., will build a 35 x 35 ft. brick addition to its laboratory. Estimated cost, \$15,000. Ford, Buck & Sheldon, 60 Prospect St., architects.

**WALLINGFORD**.—R. Wallace & Sons has awarded the contract for the construction of a 3-story, 50 x 120 ft. brick factory for the manufacture of silver, to C. P. Wooding, Jr., Wallace Ave. Estimated cost, \$50,000.

#### Florida

**JACKSONVILLE**.—The American Chemical Co., 35 East Forty-first St., New York City, will rebuild its fertilizer plant here destroyed by fire entailing a loss of \$1,000,000.

**MANATEE**.—The Sea Products Co., 1537 Chestnut St., Philadelphia, Pa., will build a factory here for the manufacture of fish leather, oil, fertilizer and etc.

#### Georgia

**COLUMBUS**.—The Union Seed & Fertilizer Co. will build a plant for the manufacture of peanut oil.

#### Illinois

**WAUKEGAN**.—The Griss-Pfleger Tanning Co. is building a 140 x 170 ft. hide house addition to its plant.

#### Indiana

**HAMMOND**.—The International Wood Products & Chemical Co., recently organized, with a capital stock of \$100,000, will operate plants in Canada and Tennessee and will also open a school of Chemical Research and be advisors to those who desire to enter the chemical field. Frank A. Gross, 376 Indiana Ave., secretary and treasurer.

**KOKOMO**.—The Kokomo Rubber Co. is building a 2-story plant on South Main St. Estimated cost, \$25,000.

#### Iowa

**CLINTON**.—The Klein Paper Co., Nineteenth Ave. and Fifth St., will build a paper mill and power plant. Estimated cost, \$175,000. J. Morrell, 410 Howes Bldg., architect.

#### Kansas

**HARRISON**.—H. W. Rodus will remove and remodel his 200-ton concentration plant known as the Texas Mill, and is in the market for sludge and slime tables, mill roofing, mill hardware, belts, drills, pipes, ore cars and track. Estimated cost, \$35,000. H. W. Rodus, manager.

**HUTCHINSON**.—The Morton Salt Co., 80 East Jackson Blvd., Chicago, Ill., will build a salt plant here, main building, three story, 50 x 140 ft. F. V. Parkins, 7524 Stewart Ave., Chicago, architect.

**MONARCH**.—The Commerce Mining & Royalty Co., Commerce, Okla., has awarded the contract for the construction of a 250-ton concentration plant to Elmer Stevens, Miami, Okla. Estimated cost, \$65,000.

**TREECE**.—The Eloosa Lead & Zinc Co. will build a 300-ton concentration plant and is in the market for sludge and slime tables,

drills, roofing, mill hardware, engine, boilers, jigs, air compressors, belts, pipe, track, cars, and ore cans. Estimated cost, \$65,000.

**TREECE**.—The Lawyers Mining Co. will build a 250-ton concentration plant and is in the market for sludge and slime tables, boiler, roofing, mill hardware, crushers, rollers, drills, ore cars, track and air compressors. Estimated cost, \$65,000. George O. Pearson, superintendent.

#### Kentucky

**COVINGTON**.—The Kelley-Koett Co. has purchased a site on West Fourth St. and will build an addition to its plant for the manufacture of X-ray machines.

#### Louisiana

**NEW ORLEANS**.—The Beners Salt Co., Inc., will open a salt mine near Anse La Butte, and is in the market for mine hoists, screens, crushers, mills, etc. R. A. Shelton, superintendent in charge.

#### Maryland

**BALTIMORE**.—The American Can Co., Maryland Trust Building, has awarded the contract for the construction of a 4-story, 38 x 140 x 176 ft., can factory on Boston and Hudson Sts., to West Construction Co., 907 American Building. Estimated cost, \$150,000. Noted July 15.

**BALTIMORE**.—J. T. Lewis Bros. Co., 1015-19 East Fayette St., has awarded the contract for the construction of a plant to include several 1- and 2-story factory buildings of various sizes, on Columbia Ave., for the manufacture of ammunition, to McVey Construction Co., Law Building.

**HUTTON**.—The Tiera Tanning Co. will build an addition to its plant. Estimated cost, \$18,000.

#### Massachusetts

**MILFORD**.—The city has awarded the contract for the construction of a sewage disposal plant, to Cenedella & Co., 68 School St.

#### Michigan

**DETROIT**.—The American By-Products & Chemical Co., 1111 Woodward St., has awarded the contract for the construction of an addition to its factory at Jefferson and Clark Aves., to L. W. Zander, 708 Fourteenth St.

**GRAND RAPIDS**.—Semet-Solvay Co., Milton Ave., Syracuse, N. Y., will build a 1- and 2-story, reinforced concrete, brick and steel picric acid plant here. Estimated cost, \$2,000,000. H. N. Cole, c/o Owners, engineer.

**SAGINAW**.—The Saginaw Malleable Iron Co. will build an addition to its plant.

**WYANDOTTE**.—The city plans to build a filtration plant of 4,000,000 gal. capacity. Estimated cost, \$175,000. W. C. Lambert, Mayor.

#### Mississippi

**PASCAGOULA**.—The city will build sanitary sewage and a disposal plant. Estimated cost, \$100,000. X. A. Kramer, May-nolia, engineer.

#### Missouri

**KANSAS CITY**.—The Zahner Manufacturing Co., 12 West Tenth St., will rebuild its plant for the manufacture of galvanized iron, recently destroyed by fire entailing a loss of \$15,000.

**ST. LOUIS**.—The American Paper Products Co. has awarded the contract for the remodeling of its plant, to J. H. Bright Contracting & Building Co., St. Louis. Estimated cost, \$3,000.

**ST. LOUIS**.—Charles L. Holman, President of Laclede Gas Light Co., has announced that procurement orders have been issued by Procurement Bureau of the Ordnance Division for the construction of two shell loading plants. One plant is to be located near Broadway just south of River des Peres, and is to be 1200 ft. long and 200 ft. wide, one story, except in center, which will be heat treating section and have a height of two or three stories, to be used for the manufacture of 155 mm. shells. Another plant will be located near plant of Scullin Steel Co. on Manchester

Ave., where 94-in. shells will be manufactured. Estimated cost of buildings and equipment \$8,000,000, which will be financed by Government and operated by gas company.

**ST. LOUIS**.—The Johnson Tin Foil & Metal Co., 6020 South Broadway, has awarded the contract for the construction of a 2-story, 80 x 170 ft. factory, to Murch Bros., Railway Exchange Building. Estimated cost, \$30,000.

**ST. LOUIS**.—The Mallinckrodt Chemical Co., 3600 North Second St., will build a 60 x 100 ft. factory for the manufacture of ether, on Second and Mallinckrodt. Estimated cost, \$25,000. A. H. Haeseler, Wainwright Building, architect.

#### Nebraska

**MERRIMAN**.—The Wyoming-Montana Co., Riverton, Wyo., has awarded the contract for the construction of a potash reduction plant here, to W. Berg Co., First National Bank Building, Omaha. Estimated cost, \$300,000.

#### New Jersey

**BRIDGETON**.—The city will build a sewage disposal plant. Estimated cost, \$3,500. W. D. Frederick, engineer.

**BRIDGETON**.—The Cumberland Glass Manufacturing Co. will build a 1-story, addition to its plant on North Laurel St. Estimated cost, \$10,000.

**CAMDEN**.—The Public Service Gas Co., 80 Park Ave., Newark, has awarded the contract for the construction of a 2-story, 36 x 78 ft. generator building and a 2-story, 29 x 43 ft. brick and brick shale reinforced concrete and brick, on Second and Cherry Sts., to Mockett Construction Co., Sixth and Market Sts. Estimated cost, \$23,000 and \$20,000 respectively.

**HARRISON**.—The Crucible Steel Co., Grant Ave., Jersey City, will build an 81 x 180 ft. brick and steel gas reduction plant on Cape May St. Estimated cost, \$85,000.

**NEWARK**.—The Atlas Refining Co., Lockwood St., is building a 2-story, 40 x 61 ft. brick oil compounding house. Estimated cost, \$15,000. Gray & Ring, architects.

**NEWARK**.—The Dye-Products & Chemical Co., 187 Pommer Ave., will build a plant on Vandevor Ave.

**PASSAIC**.—The Manhattan Rubber Co., Willett St., has awarded the contract for the construction of a 60 x 208 ft. addition to its plant to Austin Co., 16112 Euclid Ave., Cleveland, O.

**RUTHERFORD**.—The Alliance Silk Co., 180 East Seventh St., Paterson, has awarded the contract for the construction of a 4-story, concrete and brick shoe and dye mill, to J. J. Leary Construction Co., Passaic. Estimated cost, \$50,000.

#### New York

**ALBANY**.—The Patent Vulcanite Roofing Co., Tivoli St., will build a 1-story, 70 x 245 ft. factory. Estimated cost, \$35,000.

**BUFFALO**.—The Contact Process Co., Abbott Road, has awarded the contract for the construction of a 1-story, reinforced concrete, brick and steel addition to its plant, to J. Cowper Co., Inc., Buffalo. Estimated cost, \$13,500.

**LONG ISLAND CITY**.—The Ravenswood Paper Mills Co. will build a 1-story, 70 ft. addition to its plant here. Estimated cost, \$10,000.

**NIAGARA FALLS**.—The Niagara Electric Chemical Co. will build a 2-story, 25 x 224 ft. reinforced concrete, brick and steel, factory on Buffalo Ave. Estimated cost, \$50,000.

**ROCHESTER**.—The Taylor Instrument Co., 95 Adams St., has awarded the contract for the construction of a three story, 100 x 230 ft. brick and mill construction factory for the manufacture of thermometers, to Corsling & Swan Construction Co., 243 Powers Building.

#### Ohio

**CANTON**.—The city will build a sewage disposal plant including three additional Imhoff tanks, enlarging sludge beds, installing incinerator and laboratory. Estimated cost, \$50,000. W. E. Sarver, City Hall, engineer.

**CINCINNATI**.—The Nitrate Division, War Department, Washington, D. C., has awarded the contract for the construction of a nitrate plant, to the DuPont Co., Munsey Building, Washington, D. C. Cost will run into millions.

**CINCINNATI**.—The Peters Cartridge Co., First National Bank Building, has taken over the plant of the Le Blond Machine Tool Co. and is in the market for equipment for use in the manufacture of munitions.

**CLEVELAND.**—The Electric Products Co. will build a one story, 90 x 176 factory. Estimated cost, \$30,000.

**CLEVELAND.**—The Lennox Chemical Co., 1201 East 15th St., will build a one story, 90 x 400 ft., brick and steel factory.

**CLEVELAND.**—The Phoenix Oil Co., 2554 West Fifth St., has purchased a site on Perry Ave. and will build a factory. Estimated cost, \$60,000.

**TOLEDO.**—The Doehler Die Castings Co., manufacturers of hand grenades, depth bombs, and parts of gas masks, will build a one story, 60 ft. addition to its foundry and a two story, 50 x 150 ft. factory on Smead Ave. and the Lake Shore R. R.

**WARREN.**—The Gregory Rubber Co., 144 North Union Ave., Akron, will build a plant here, the main unit of which will be a two story, 50 x 100 ft. factory. Stalker & Hemp, 706 Western Reserve Bank Building, local representatives.

### Oklahoma

**CARDIN.**—The Healdton Mining Co. will build a 200-ton concentration plant and is in the market for sludge and slime tables, crushers, cars, track, engine, belts, mill hardware, roofing, mill lumber and air compressors. Estimated cost, \$65,000.

**MONARCH.**—The Miami Royal Mining Co., Miami, will build a 300-ton concentration plant and is in the market for sludge and slime tables, mill hardware, lumber, crushers, air compressors, drills, tubes, pipes, conveyors, engines and boilers. Estimated cost, \$65,000.

**PAWBUKA.**—The city plans to build filtration plant, Archer & Stevens, New England Bank Bldg., Kansas City, Mo., engineers.

**QUAPAW.**—The Alamo Lead & Zinc Co. will build a 200-ton concentration plant and is in the market for sludge and slime tables, engine, boiler, lumber, roofing, air compressors, fans, drills, belts, mill hardware, crushers, track, ore cars and conveyors. Estimated cost, \$30,000. J. T. Burgher, Dallas, Texas, superintendent.

**ST. LOUIS.**—The Huttig Lead & Zinc Co., 328 Frisco Building, Joplin, Mo., will rebuild its 200-ton concentration plant and is in the market for sludge and slime tables, engine, boiler, lumber, roofing, air compressors, drills, belts, track, ore cars, crushers, slime and sludge tables, engine, boilers, pipes, scales, acid roofing. Estimated cost, \$70,000. R. M. Simrall, superintendent.

### Oregon

**PORTLAND.**—The Viking Marine Paint Co., Sherlock Bldg., has awarded the contract for building a one story, 40 x 70 ft. reinforced concrete, brick and steel factory on Industrial Center, to Rasmussen-Grace Co., 180 Burnside St. Estimated cost, \$12,500.

### Pennsylvania

**BEAVER FALLS.** The Meltrup Steel Products Co. has purchased the plant of the Pittsburgh Steel Co. and will convert same into a producing plant for its own use.

**CORNWELLS.** The Badenhausen Boiler Co. will build a one story, 195 x 345 and 200 x 350 ft. machine shop and manufacturing plant. Estimated cost, \$300,000.

**MT. UNION.**—The Aetna Explosive Co., Inc., 120 Broadway, New York City, is rebuilding its factory here, including new buildings, which were recently destroyed by fire. Estimated cost, \$200,000.

**PHILADELPHIA.**—The E. G. Budd Manufacturing Co., Twenty-fifth and Huntington Sts., has awarded the contract for the construction of a one story, 70 x 145 ft., brick, steel piling plant to Barclay, White Co., 1713 Sansom St. Estimated cost, \$25,000.

**PHILADELPHIA.**—The Dermatological Research Co., Lightner and Naundine Sts., will build a three story, concrete and brick medical research building. Estimated cost, \$15,000. J. C. Piedstein, Penfield Building, engineer.

**PHILADELPHIA.**—McNeely 1732 North Randolph St. has awarded the contract for the construction of a three story, 8 x 13 ft. addition to its factory for the manufacture of glass and to Stewart Bros., 2238 North Orkney St. Estimated cost, \$5000.

**PITTSBURGH.**—The Jones & Loughlin Steel Co. will build a one story, hydroproduct coking plant. Estimated cost, \$4,000.

### Rhode Island

**WOONSOCKET.**—The Electric Dye Works, 229 Perry Ave., has awarded the contract for the construction of a two story, 72 x 88 ft. plant.

### South Carolina

**CHARLESTON.**—The Charleston Heights Corporation, 272 Meeting St., has awarded the contract for the construction of a sewage disposal plant to McGrady Bros. & Cheves.

**GREENVILLE.**—The Empire Rubber Manufacturing Co. will build a plant for the manufacture of rubber shoes, canning rubbers and other products.

### Tennessee

**ASBURY.**—The Knoxville Lime, Sand & Transportation Co., Knoxville, Tenn., will rebuild its lime plant recently destroyed by fire entailing a loss of \$6000.

### Texas

**HOUSTON.**—The Universal Tire & Rubber Co. has awarded the contract for the construction of a 100 x 200 ft., reinforced-concrete and steel plant. Estimated cost, \$100,000.

**PORT NECHES.**—G. D. Anderson, 2215 Calder St., Beaumont, has purchased a 672 acre site on Neches River and will build an oil refinery.

### Virginia

**HAMPTON.**—The Bureau of Yards and Dockways Department, Washington, D. C., has awarded the contract for the construction of an addition to the White Gray at the Naval Operating Base, to Wilson, Rie & Company, American Bank Building, Norfolk. Estimated cost, \$17,800.

### West Virginia

**WESTON.**—The city will build a sewage disposal plant. Estimated cost, \$15,000.

### Wisconsin

**STEVENS POINT.**—G. W. Mead will build a one and two story, 100 x 400 ft. mill for the manufacture of tissue paper. Estimated cost between \$25,000 and \$50,000. L. A. DeGuere, Stevens Point, engr.

### Canada

#### British Columbia

**BURNABY.**—The Burnaby Oil Co. will build a plant here. Estimated cost, \$100,000.

#### Ontario

**KITCHENER.**—The Canadian Consolidated Rubber Co., 137 King St., will build an addition to its factory. Estimated cost, \$10,000. A. C. Copeland, engineer.

**TORONTO.**—W. Harris & Co., Danforth Ave., has purchased a site on the Ashbridges Bay Industrial site and will build a plant for the manufacture of glue. Estimated cost, \$100,000.

#### Quebec

**DRUMMONDVILLE.**—The Drummondville Match Co. has awarded the contract for the construction of a factory to J. A. Nadeau. Estimated cost, \$100,000.

**WINDSOR MILLS.**—The Canadian Explosives, Ltd., 120 St. James St., Montreal, will rebuild its plant which was totally destroyed by fire entailing a loss of \$60,000.

## Industrial Notes

**THE TOLEDO FURNACE CO.** is producing gas from its coke oven plant which is being used by a number of industrial plants at Toledo, Ohio.

**THE TOLEDO RAILWAY AND CO.** has purchased an 18-acre site at Seven Thomas meters built by the Cutler-Hammer Mfg. Co., Milwaukee, are in use for measuring it.

**THE H. KOPPERS CO.,** Pittsburgh, Pa., erected and placed in operation sixty coke ovens at the plant of the Bethlehem Steel Corporation, which makes a total of 180 ovens in operation.

**THE WESTERN STEEL CAR AND FOUNDRY CO.** at Hegewisch, Chicago, Ill., has installed two single-phase Snyder electric furnaces, to be operated together on a polyphase current system. These two furnaces were built by the Industrial Electric Furnace Company, Chicago, Ill., and are each of one and one-half tons capacity. They are designed for acid operation on steel castings, and unusually good results are expected from this method of operating single-phase furnaces on a polyphase system.

**THE FAULKNER COMPANY,** Rochester, N. Y., has appointed Lawrence C. Stahlbrodt to take charge of its publicity department. Mr. Stahlbrodt was originally educated in chemistry but has been engaged for the past six years in publicity work. He was last connected with The Hurst Engraving Company of Rochester.

**THE CUTLER-HAMMER MANUFACTURING CO.,** Milwaukee, Wis., manufacturers of electric controlling devices, held their eleventh annual picnic under the direction of the employees' activities committee at Waukegan, Ill., near Lake Michigan, July 27. A program of athletic events for boys and girls, both young and old, was provided; prizes consisting of various amounts of money. A large number of employees attended with their families.

**LAW AND COMPANY,** Consulting Chemists, for the past fifteen years, known as Picard-Law Company, have moved their Atlanta (Ga.) laboratories to larger quarters in the Walton Building. The company shall continue their oil, mill and fertilizer specialties and wish to announce that they are especially equipped to deal with problems in connection with Georgia mineral developments, especially kaolin, fuller's earth, hauxite and pyrites.

**GENERAL CHEMICAL COMPANY** reports that the period of six months ended June 30, 1918, showed total profits of \$5,250,468, as compared with \$5,558,938 for the same period one year ago. The balance available for dividends amounted to \$5,262,468, a decrease of \$146,470, and the balance for common dividends after payment of the usual preferred dividends was equivalent to \$29.00 a share for the six-month period, as compared with \$29.10 a share for the same period a year ago.

The sum of \$2,000,000 was written off for depreciation as compared with half that amount for 1917.

**THE CASE MANUFACTURING CORPORATION,** Denver, Colo., announces that Mrs. W. W. Case, Sr., Fred McL. Strout, Theodore W. Muckle and Seth Parlin, all formerly of the Denver Fire Clay Co., have organized a new company to manufacture oil burners and oil furnaces which were invented and perfected by the late W. W. Case, Sr., former president of the Denver Fire Clay Company.

**THE ASPROMET COMPANY,** Pittsburgh, Pa., announce the opening of a Washington, D. C. office in the Munsey Building, Mr. O. C. Robinson, president of the district manager and the office will also be under the personal supervision of Mr. H. E. Marks, general sales manager.

**THE BETHLEHEM STEEL CO.,** Steelton, Pa., has recently put in operation a new battery of 50 Koppers by-product coke ovens. The H. Koppers Co., of Pittsburgh, began the construction work in November, 1916. The ovens have an individual capacity of 123 tons each with a combined output of 700 new tons of coke per day in 18 hours coking time, or 1000 tons on a 24-hour basis.

**THE THOMAS FURNACE & IRON CO.,** Easton, Pa., is planning to put its Heltetown furnace in full operation very shortly.

## Manufacturers' Catalogs

**THE UNITED FILTERS CORPORATION,** Salt Lake City, Utah: Bulletin No. 103 on the Sweetland filter, laboratory trunnion type, designed especially for the use of small scale development work, research laboratories, industrial and college laboratories, etc. This pamphlet also gives a suggested arrangement for installing the Sweetland laboratory trunnion filter, operation, and special features of operation.

**THE H. KOPPERS CO.,** Pittsburgh, Pa., has issued a little pamphlet on Nonpareil insulating brick for furnaces and ovens which they will be glad to distribute to anyone who charges on request.

**THE WORTHINGTON PUMP AND MACHINE CORPORATION,** 115 Broadway, New York: Deane Bulletin D-702, May, 1918, describing vertical triplex power pumps, single and double acting, and a 56-page bulletin and is well illustrated.

**THE CUTLER-HAMMER MANUFACTURING CO.,** Milwaukee, Wis.: Booklet A, June, 1918, on motor-operated brakes for alternating current service.

**THE WATERBURY LUMBER CO.,** 173 Milk Street, Boston, Mass., have on hand a number of reprints of Mr. F. E. Lieben-thaler's article on "Intensive Toluol Production" which will be glad to supply to anyone interested.

**THE WELLMAN-SKEWER-MORGAN COMPANY,** East 70th St. and Central Ave., Cleveland, Ohio, Bulletin No. 10, dated July, 1918, on W-34 coke oven, its construction, and illustrating some of its installations.

**THE BROWN INSTRUMENT COMPANY,** Philadelphia, Pa.: An 80-page catalog describing the line of Brown instruments and recording instruments and high-temperature measuring instruments. A copy will be sent on application to anyone interested.

## Fourth Liberty Loan

### To Be a Victory Loan

NEXT month the Government will call upon us to support the fourth great loan to aid in winning the war, and the opportunity to help should be acclaimed with joy by every loyal American. If pride in the achievement of our troops is ever to find expression, and if we are determined to see that their sacrifices have not been made in vain, now is the time to act. The nearer we approach the day of victory, the greater the necessity for unwavering support of our cause. Thus the coming loan will be a real test of loyalty and confidence.

We want to be able to look every returning soldier squarely in the eye and feel that we matched his service with our dollars. Over one and one-half million of our troops are now abroad, and if they need billions of dollars to furnish them food and munitions they should but have to make their needs known to have them supplied. The issue of bonds for the fourth loan probably will equal or exceed six billions of dollars. Taxation will account for another eight billions, but if our war program for the fiscal year ending June 30, 1919, calls for twenty-four billions we will still have some money to raise.

These sums should not stagger us, for they are but a fraction of our national resources which, as Thomas W. Lamont recently pointed out, were estimated at the beginning of the war at \$250,000,000,000. The total sum derived from Government securities to date is but \$9,978,785,000, so that we still have plenty of reserve. When the fourth loan is called for on September 28, let us make our subscriptions part of the day's business and return to our task of winning the war as speedily as possible.

## Distinguishing Between Essentials and Non-Essentials

ONE of the clearest recollections of our "prep" days in chemistry is the wise injunction given by an excellent teacher, to "learn to distinguish between essentials and non-essentials." Specially applicable to the study of science and the cultivation of keen observation, the lesson is useful wherever efficiency is paramount, whether it be in the conduct of a government at war or in the pursuit of our usual vocations.

Early in our participation in the war a great deal was said about essential and non-essential industries, and there was much speculation as to how such classification could be made. Obviously a hard and fast line could not be drawn, and we believe there would have been less confusion and misunderstanding if it had

been made plain that the essentiality of different industries in war time is a relative matter and that conditions were likely to change as time went on. Emphasis should have been laid on the fact that different lines of business were *more or less* essential to the winning of the war, and that the classification was certain to change from time to time.

With accumulated experience we have adjusted ourselves to the rulings of the War Industries Board because we have recognized the necessity of centralizing control in one body; also we have been impressed with the sanity of most of the Board's rulings. Furthermore, the spirit of pessimism which earlier prevailed on account of the fear that the list of essential industries would become more and more restricted, may now give way to optimism over the fact that the list is actually expanding. The War Industries Board is formulating a new list of "preferred" industries, which will be about twice as long as the one issued last April containing thirty-two classes. War needs have actually expanded, and civilian demands also have pressed for relief.

The preference list will be a key to the relative importance of the country's manifold industries. That it will be fair and based on sound judgment is assured from the fact that the values are determined by surveys of national needs. Once established, the list will be maintained by a system of priority in determining the use of the six basic elements of industry which are: material, facilities, fuel, transportation, labor and capital.

The publication of the new list will do more than determine the relative essentiality of different lines of business: it will draw a line for the enforcement of the work-or-fight ruling of the War Department. Men, otherwise exempt, who are engaged in any of the preferred industries will be regarded as engaged in war work, and therefore contributing as much to the winning of the war as though they were fighting. It looks as though we are distinguishing quite clearly between essentials and non-essentials.

### Chemical Exposition to Be Held This Month

RUMOR has been rife to the effect that the Fourth National Exposition of Chemical Industries would have to be abandoned because the Government had requisitioned Grand Central Palace for a base hospital. We are glad to be able to announce that, although the Palace is to be taken over by the Government, the plan will not interfere with the holding of the Exposition as planned for the week of September 23. Mr. Alfred I. duPont, owner of the leasehold on Grand Central Palace, recently announced that he had met the Government's request for the building and had notified tenants to vacate by September 15. At the same time it was made known that the Government would not require that portion of the building used for the exposition until October 1, by which time the exhibits could be removed. Meanwhile plans that have been under way for almost a year indicate that the exposition will be larger and better than ever, and will fittingly represent the industry which is growing so rapidly.

### Chemistry in Modern Warfare

THE reader will find much of interest and suggestion in the article, published elsewhere in this issue, describing the phenomenal growth of the Chemical Warfare Service, National Army. The title of the Service itself is a tribute to the importance of the science and a recognition of the extent to which chemists have been called to the colors. History records the stink-pot of the Chinese as a device for gas warfare, but we have no previous knowledge of a corps of eminent chemists engaged in research to discover the most effective gases for rendering an adversary *hors de combat*; nor of large factories devoted to the making of the said gases; nor of shell-filling stations where missiles are charged with the deadly stuff. All this has been reserved for the year of grace 1918 when the more civilized nations of the earth are trying to annihilate Hohenzollernism with its own diabolical devices.

Little has been said in public about our work in gas warfare because secrecy is essential to success. The strategic value of gas warfare lies in the element of surprise. If the enemy can be caught without protection against a new gas, its use will prove effective until he can determine its nature and provide means for nullifying its action. Once he has succeeded in developing defensive measures, further attacks with that particular gas may not prove very effective. Hence the impossibility of publishing the results of the research in gas offense. This, however, need not prevent a full knowledge on the part of the chemical profession of the magnificent work which its members are doing in the present war. The commissioned personnel is practically a list of chemical leaders in the United States.

### Germany's Finger in the Platinum Pie

OUR editorial under this caption in our last issue has evoked letters of protest from Charles Engelhard and Baker & Co., Inc., which we are glad to accord space in the columns regularly devoted to the views and comments of our readers.

### Gold Mining An Essential Industry

THE Priorities Board of the War Industries Board has formally resolved that gold mining is an essential war industry, and as such is entitled to certain preferential treatment. Accordingly the powers of the Board will be exercised to see that gold mines get tools, machinery, equipment, transportation service, fuel and labor.

Of course the War Industries Board is not responsible for the predicament of gold mining, neither can it alleviate its sufferings by resolution, although the latter will obviate the cost of delays which are often serious. The gold mining industry needs something more than resolutions or even fuel, labor and supplies. It needs these things at normal cost or else an enhanced value of its product. Since the latter is not likely to materialize, the next form of assistance which suggests itself is the bonus. The closer the cost of producing gold approaches \$20.67 per ounce, the sooner we will

have to choose between supporting the industry or seeing it languish and die.

At the beginning of the war we pointed out the economic advantage accruing to the Allies from the fact that they controlled the production of gold. Great Britain alone controls 60 per cent of the world's output, and the Allies today control well over 90 per cent. If this item is an advantage now, it must prove even more effective after the war. And if we expect to retain that advantage in the face of a decreasing production of gold we must take measures for support of the industry.

Gold production is falling off, the world over. Transvaal production for May 1918 was only 741,317 fine ounces compared with 779,385 fine ounces in May, 1917. United States production has declined from a value of \$101,000,000 in 1915 to \$84,000,000 in 1917.

Gold producers in the United States recently met at Reno, Nevada to consider what should be done to avert collapse of the industry. It is quite evident from reports of the meeting that sanity and good judgment prevailed. The assembly expressed the frank opinion that, without assistance, gold mining is likely to fall off alarmingly in this country. Government relief for producers to correspond with the increased cost of production was held to be a necessity, but any thought of altering the value of gold or disturbing our financial system was deprecated. Sound money was recognized as absolutely essential even if gold mines have to close for a time.

### Iron Contents Of Iron Ores

THE fact that iron industries throughout the world thrive under quite divergent conditions suggests that there are compensations. Industries that are well fixed in some respects are not nearly so well fixed in others. If it were otherwise, the competitive condition could hardly be maintained as well as it has been.

Thus one observes that Sweden has large reserves of iron ore of exceptional purity, practically the plain oxide, but some of the ores lie within the Arctic Circle, and there is no fuel except charcoal and "white coal" which lately has been applied to advantage. Sweden has iron-producing companies that have been in continuous existence for several centuries. Then there is the very low iron content of the Minette ores of Lorraine, but by admixture a self-fluxing charge can be made. Great Britain supports an iron industry with both classes, extremely lean native ores and very rich ores brought from Spain. India, China and Japan have certain advantages and disadvantages, and if they had an even start with Great Britain or even the United States, they would now have flourishing iron industries of very considerable size.

In each of these cases there is a mixture of advantages and disadvantages and so each has a place as an iron producer and, except in the case of Sweden, as a steel producer of corresponding size. Here in the United States we have had a situation which has been frequently looked upon as follows: In the South and in Virginia we have rather lean ores which on account of their close association with coal and limestone deposits can be worked to advantage and the product

shipped very considerable distances. Also we have the rich Lake Superior deposits, not associated with coal or limestone, which on account of their richness can be transported great distances, say a thousand miles, for smelting. Then, not to mention various smaller districts, we have the Atlantic seaboard, which can bring rich ores from Cuba and Chile and on occasion from Sweden, and not absolutely barred from using Lake Superior ore.

This is, perhaps, the common picture, but as to the Lake Superior ores it is based partly upon conditions that have been slipping away for well nigh two decades. That is a fact that must be faced by the heads of producing concerns using Lake Superior ores and also by those who contemplate establishing new plants dependent upon those ores. From time to time decisions must be made by the captains of industry having regard to the analysis and physical properties of the Lake Superior iron ores available.

To metallurgical and mechanical engineers it is a fact that must be present all the time and must affect practically the daily work. The development of each of the Lake Superior ranges was predicated upon iron contents, natural state, well up in the sixties. There remains some rich ore, but not nearly as much as formerly, and with the quintupling of the production in a double decade the mass of rich ore has been so greatly diluted that it hardly makes an impress in the final reckoning. That reckoning is compiled annually by the Lake Superior Iron Ore Association, whose latest report shows that the average iron content of the 62,616,045 gross tons of iron ore shipped from the Lake Superior region in 1917 was 51.3812 per cent, natural state, as shipped. That is many units removed from the iron content that made the Lake Superior region famous. To put the matter flatly, if until this date the Lake Superior region had been shut off from human ken, and we had our present iron-producing districts, Alabama, Virginia, Atlantic seaboard etc., and suddenly these 51 per cent Lake Superior ores were offered, there would be no great rush to build an iron and steel industry upon them.

The industry, however, is strong, vigorous and growing. The credit must be given not to Nature but to the mechanical and metallurgical engineers, to their steam shovels which were handling more overburden or ore per shovel than those whose achievements in digging the Panama Canal attracted world-wide attention, to the wonderful Lake carriers receiving and discharging in a very few hours burdens running into five figures, to the automatic appliances at 600-ton blast furnaces, to all the metallurgical and mechanical devices used in converting Lake Superior ores into finished steel products. The average content of Lake ores shipped has been declining at the rate of about one unit in every three or four years and there is no reason to expect that the decline will not continue, though probably at a somewhat lower rate in future. This decline is going to keep the engineers busy if the industry based upon Lake Superior iron ore is to continue to grow in decades to come, or even to maintain its present tonnage. The industry cannot rest with the methods and appliances it has now. Year by year improvements must be made to compensate for declining iron units in an ore that must often travel more than a thousand miles.

## Readers' Views and Comments

### Need of Optical Instruments in Industrial Laboratories

*To the Editor of Chemical & Metallurgical Engineering*

SIR:—A few days ago the writer learned from the chief chemist of a well known packing house, that at this time they are in need of a number of refractometers.

Now I can recall at least three well known physics laboratories that are in possession of at least one good refractometer each, and moreover I am quite certain that these instruments are not in constant use.

It seems to me, therefore, that some definite relation should exist between these laboratories and the essential industries. Not only should this apply to refractometers but to other optical instruments that are difficult to obtain just now. With our small classes and no research work many polariscopes, colorimeters, optical pyrometers, etc., might be turned over to the industries for the duration of the war.

Personally, I see no reason whatever why the Government might not ask for a list of all such instruments from the physics laboratories of the country, in order that, should it seem desirable, these instruments may be called for so that the industries might have the use of them.

Practically all of them were brought into this country duty-free, so that the industries could afford to buy them from colleges at the prices they paid for them and the colleges would thereby lose nothing.

Again they could, to be sure, be loaned for the period of the war.

G. A. SHOOK.

Williamstown, Mass.

### Germany's Finger in the Platinum Pie

*To the Editor of Chemical & Metallurgical Engineering*

SIR:—I desire to protest most energetically against the reference to me contained in your recent editorial, entitled "Germany's Finger in the Platinum Pie," and I submit that such an article should not have been published, without giving me an opportunity to enlighten you in regard to the matters referred to therein, as to which you confess ignorance.

I did not come to this country as the emissary or agent of any one. I have been connected with Baker & Co., Inc., and the American Platinum Works, since their organization and no German capital was ever employed directly or indirectly in their expansion, unless a former one-fifth interest in their capital stock can be so regarded.

As to the Draper incident, which you feature so prominently in your article, I would state that my advice was not asked in the matter, nor offered, nor had I at that time even met Mr. Summers.

I have lived in this country for over twenty-five years, have been an American citizen for many years and yield to no one in my admiration of our laws and institutions. I have never served in any official capacity to our Government, and, like any other loyal American citizen, have answered in the most conscientious

manner only such questions as were put before me, thus endeavoring to give to our Government the benefit of any special knowledge I might possess in regard to platinum.

I have nothing to fear or conceal. My record is well known to our Government, and I demand only justice from my fellow-citizens.

CHARLES ENGELHARD

New York.

*To the Editor of Chemical & Metallurgical Engineering*

SIR:—Your editorial entitled "Germany's Finger in the Platinum Pie," which appeared in your issue of August 15, in so far as it suggests that the undersigned company has been or is subject to German influence, is unjust, misleading and directly contrary to facts. None of our stock is now owned, or since nearly a year previous to our entry into the war, has been owned by any German or ally of Germany, nor does any enemy or ally of an enemy influence or control our management directly or indirectly in the slightest degree.

At no time in our history has any German interest owned more than one-fifth of our stock, nor did such stock exercise any special influence in our management, nor has German capital or credit contributed in any other respect to our expansion or growth. On the other hand, we include among our largest stockholders Mr. Charles W. Baker and the Estate of Mr. Cyrus O. Baker, of Newark, the well-known English firm of Johnson, Matthey & Co., Ltd., and the French firm now Quennessen, de Belmont, Legendre & Co. The Bakers are of old American stock; Johnson, Matthey & Co., Ltd., are the direct representatives of the British Government as regards platinum, and needless to say would not be associated with any pro-German interests in this country.

BAKER & COMPANY, INC.

Newark, N. J.

### Dye-Stuff Symposium at Cleveland

*To the Editor of Chemical & Metallurgical Engineering*

SIR:—At the American Chemical Society meeting in Cleveland there will be a dye-stuff symposium on Tuesday at 2 o'clock, September 10, which will also continue over into Wednesday morning.

All phases of the chemistry of dye-stuffs will be under discussion and a number of papers by experts in this line will be presented. The meeting will also be thrown open to general discussion.

It is expected that out of this initial dye-stuff symposium there will arise regular meetings of those interested in the chemistry of dye-stuffs at the conventions of the American Chemical Society for the purpose of discussing and encouraging the development of the chemistry of these materials.

As this phase of the dye-stuff industry is so essential to its ultimate development, we are asking hearty cooperation of all interested.

R. NORRIS SHREVE,

Chairman, Dye-Stuff Symposium

Calco Chemical Company,  
Bound Brook, N. J.

## Western Chemical and Metallurgical Field

### American Zinc Institute.

OVER 150 men interested in the mining and smelting of zinc met in St. Louis July 29 to consider ways and means of bettering the economic condition of the metal through their coöperative action. The result of this conference, said to be the first in the history of zinc mining, was the appointment of a committee to effect the permanent organization of the American Zinc Institute. This committee on organization consists of the following men, well known to the industry: Victor Rakowsky, Joplin, Mo.; J. L. Bruce, Butte and Superior Mining Co., Butte, Mont.; E. H. Wolff, Illinois Zinc Co., Peru, Ill.; A. B. McMillan, Edgar Zinc Co., St. Louis, Mo.; Chas. T. Orr, Athletic Mining and Spelter Co., Webb City, Mo.; A. P. Cobb, New Jersey Zinc Co., New York City; and W. F. Rossman, American Zinc, Lead and Smelting Co., St. Louis, Mo.

The recent history of the zinc market is well known. It was the first common metal to be demanded in unusual quantities by our allies, but over a year ago the ready expansion of American mines and mills changed an excess demand into an overproduction, and the price rapidly fell. The low point of 6½ was higher than the normal pre-war average of 5½, but increasing commodity process caused sharp curtailment by producers.

The problems awaiting solution by the American Zinc Institute may be realized when one considers the difficulties which the American industry are now weathering, despite the embargo on ore shipments from abroad and the exclusion of the Mexican ore by refusing it railway equipment for transportation from ports of entry. With the field absolutely pre-empted there is today but 60 per cent of the present live distilling capacity operating. Prospective American exporters cannot realize too early that when transportation is normalized the severest competition will have to be met in foreign markets. At present it may be easier to exact a better price for metal than to use real brains to lower its cost; but after the war the decisions of the War Industries Board will have small interest to the Spaniard who asks for specifications. If it is to succeed, the energies of the Institute may well be diverted from the monopolistic fixation of prices and expended on the larger labors of research for increased mining and metallurgical efficiency and for new uses for the metal, and to acquire and disseminate among their membership and the general public statistical and other information as to production, costs, and uses.

Other metallurgical and chemical industries may well profit by the experience in zinc. The soaring price of a war bride has killed that one market absolutely necessary for continued operation, the steady, small-lot, home consumption. If copper, steel, lumber and others follow the example of zinc, the most drastic price cutting will be necessary at the war's end in order to re-educate the consumers to the old-fashioned uses of common commodities.

### Prices Fixed for Sheet and Plate Zinc

The President has approved an agreement made between the producers of sheet and plate zinc and the Price Fixing Committee of the War Industries Board (after investigations by this committee in conjunction with the Federal Trade Commission as to the cost of production) that the maximum base price of fourteen cents per pound f.o.b. plant for plate zinc, and fifteen cents per pound f.o.b. plant for sheet zinc, shall be continued on deliveries from Sept. 1, 1918, to Jan. 1, 1919, subject to the usual trade discounts and extras or differentials that were in effect Feb. 13, 1918. These discounts and extras shall be effective on all contracts executed between Feb. 13, 1918, to Jan. 1, 1919. Sheet zinc shall be considered as including all gages of one-eighth inch thickness and less and plate zinc as including all gages thicker.

The conditions are, as formerly: First, that the producers of plate and sheet zinc will not reduce the wages now being paid; second, they will sell to the Allies, to the public, and to the Government at the same price; third, that they will take the necessary measures, under the direction of the War Industries Board, in the distribution of plate and sheet zinc to prevent it from falling into the hands of speculators who might increase the price to the public; and fourth, that they pledge themselves to exert every effort necessary to keep up the production of plate and sheet zinc so as to insure an adequate supply as long as the war lasts.

### Work Suspended on Muscle Shoals Hydro-electric Power Project

The War Department after consultation with the War Industries Board has ordered the suspension of work on the dam and other construction for the hydro-electric power project at Muscle Shoals, Alabama. In making this statement to the Washington correspondent of *CHEMICAL & METALLURGICAL ENGINEERING*, Benedict Crowell, assistant secretary of war, pointed out that no stoppage of work on the building of the nitrate plant at Muscle Shoals is in contemplation nor is there any contemplation of stoppage of work at the Cincinnati, Toledo and other plants. In fact there are estimates obtainable in Washington that the nitrate plant at Muscle Shoals will be placed in production this year.

While the work on the hydro-electric development at Muscle Shoals is announced as being suspended temporarily, it is nevertheless the belief in Washington that this work has been suspended for the period of the war. Three years would be required to complete this work and it is plainly stated at the War Department that in view of this fact the work is of a non-essential character. In other words, the belief is entertained in Washington that the war will be over before this particular power plant could be placed in production.

The decision to abandon the Muscle Shoals hydro-electric plant came as the result of a request to the War Industries Board that this project be placed on the list for priority as an essential undertaking but the Board held that the labor and material being used there and in contemplation are urgently required to meet more immediate war demands. In this view the War Department has concurred.

## Emergency Bill in Congress for Federal Control of Power Resources

**T.** W. SIMS, chairman of the House committee on interstate and foreign commerce, has introduced in the House of Representatives a bill "to provide further for the national security and defense and for the more effective prosecution of the war by furnishing means for the better utilization of the existing sources of electrical and mechanical power and for the development of new sources of such power." The bill provides the sum of \$150,000 for administrative expenses and provides the sum of \$200,000,000 for the purchase and building of power plants.

The proposed legislation is to be known as the emergency power act. It is not to be confused with the water-power bill now pending in the House of Representatives and will not be considered in connection with that bill, which is all ready on the floor of the House, while the emergency power act has but just been referred to the committee. Hearings on the emergency power act were begun before the House interstate and foreign commerce committee on Aug. 23. The War Industries Board, the Treasury Department and the Shipping Board served notice on the committee that it was desired that representatives of these governmental agencies should testify at the hearings.

In making the bill public, Representative Sims issued a statement in part as follows:

We are facing a power shortage which is and for some time past has been acute and is hampering our progress on war production. So this measure authorizes the President to erect power stations near the coal mines and at other points where he may deem them necessary, or to extend financial aid to persons or corporations about to do so, and therefore desiring to secure results of tremendous, immediate and inestimable value to America. It is considered necessary by representatives of the administration, by representatives of the great power companies and by economists who attacked the problem from various viewpoints, and is endorsed by all of them.

This bill must not be misunderstood as in any wise taking the place of the water-power bill now before the House. That is in its nature a peace-time measure, and the provisions of the two do not conflict. The plans are to confer upon the President all necessary power to deal with the urgent power situation properly and effectively and to place at his disposal sufficient funds with which to assure adequate operation. The bill contains:

1. Increased production of power available for war industries and shipyards.
2. Economy in the use of fuel.
3. Reduction in the railroad freight load, especially in the fuel load.
4. Increased production of metallurgical coke, toluol, ammoniacal liquor, all recovered from coal.

The bill grants sweeping authority to the President and includes penalties of imprisonment or fine or both for any who knowingly neglect or refuse to comply with any order or requisition made by the President or any officer or agency designated or created under the act.

**New Electric Smelting Furnaces in Sweden.**—Having doubled its capital and made it \$724,000 the Aktiebolaget Porjus Smältverks proposes to build two electric smelting furnaces this summer. The company has already three furnaces in operation. The company's power is secured from the Porjus waterfall. It expects to manufacture 20,000 metric tons of pig iron each year. —*Consular Reports.*

## Electric Furnace Manufacturers Confer on War Problems

**E**LECTRIC furnace manufacturers who are organized under the name of the Electric Furnace Industries War Service Committee, met in New York City on Aug. 20 to consider what steps should be taken for their welfare, in view of the possibility of action by the War Industries Committee curtailing construction of new plants for steel castings. As outlined in *CHEMICAL & METALLURGICAL ENGINEERING*, Aug. 15, page 171, the electric furnace industry is confronted with the fact that the War Industries Board may find it necessary to grant no new permits for electric steel casting plants, due to the fact that there is already ample casting capacity.

The Executive Committee of the organization, comprising G. H. Clamer, F. N. Castle, C. P. Fletcher and F. J. Ryan, discussed the entire situation with the following members of the association: C. H. Booth, F. W. Brooke, H. A. DeFries, C. H. VomBaur, T. F. Baily and D. D. Miller. Although considerable time was devoted to a discussion of the electrode situation, the association properly concluded that this phase of the matter was not of immediate concern to electric furnace manufacturers, but that the controlling factor was whether or not there is already an ample capacity in the country for steel castings. Being in agreement on this point the meeting passed a resolution to the effect that the Executive Committee of the organization should confer with the Steel Division of the War Industries Board to ascertain whether or not there is now a shortage of capacity for steel castings and whether new capacity is essential. The Executive Committee is to report its findings to the members of the organization and further action is to be taken after this report is received. All of the furnace manufacturers are in agreement to abandon further efforts to establish new electric steel casting plants if the War Industries Board satisfies them that there is now ample supply for all needs.

## Ordnance Board on Metallurgical Matters

In order to assure the more complete coordination of the various Ordnance Departmental activities along metallurgical lines, it has been decided to establish a Board on Metallurgical Matters. The appointment of this board will also assure the complete coordination of similar activities of the different divisions of the War Department and the War Industries Board.

The personnel of the board is as follows: Dr. G. W. Sargent, Engineering Division, chairman; Lt. Col. W. P. Barba, Production Division; Major A. E. White, Inspection Division, representing the Ordnance Department; Lt. Col. F. B. Richards, of the office of the Assistant Secretary of War; Mr. L. L. Summers, representing the War Industries Board, and Mr. William H. Smith, representing the manufacturers.

The board will act not only for the various sections of the Ordnance Department but also in connection with the manufacturers working for and with the department in the production of war material, and will gather the most recent and complete information on all metallurgical products.

## Disposition of Chemists in the Army

**A**S A RESULT of a letter from the Adjutant General of the Army, dated May 28, 1918, 1749 chemists in the army have been reported on. Of these the report of actions to August 1, 1918, shows that 281 were ordered to remain with their military organization because they were already performing chemical duties; 34 were requested to remain with their military organization because they were more useful in the military work which they were doing; 12 were furloughed back to industry; 165 were not chemists in the true sense of the word and were, therefore, ordered back to the line; and 1294 are now placed in actual chemical work. There were being held for further investigation of their qualifications on August 1, 1918, 432 men. The remaining 23 men were unavailable for transfer, because they had already received their overseas orders.

The 1294 men, who would otherwise be serving in a purely military capacity and whose chemical training is now being utilized in chemical work, have, therefore, been saved from waste. Each case has been considered individually, the man's qualifications and experience have been studied with care, the needs of the Government plants and bureaus have been considered with equal care, and each man has been assigned to the position for which his training and qualifications seem to fit him best. Undoubtedly, there have been some cases in which square pegs have been fitted into round holes, but, on the whole, it is felt that the adjustments have been made as well as could be expected under the circumstances. Where readjustment is necessary, subsequent action will be taken.

## Enemy Patent Licenses Issued by Federal Trade Commission

Following is a complete list of enemy patent licenses issued by the Federal Trade Commission. It is significant of the activity of the German people along chemical lines to note that over 80 per cent of the licenses granted are for patented chemical processes and products not hitherto used or produced by American chemists.

### PATENT LICENSES ISSUED

Non-exclusive. The Dermatological Research Laboratories, 1818 Lombard St., Philadelphia, Pa. Arsphenamine, Nov. 26, 1917. Neo-arsphenamine, Mar. 4, 1918.

Non-exclusive. Takamine Laboratory, Inc., 120 Broadway, New York City. Arsphenamine, Nov. 26, 1917. Neo-arsphenamine, Mar. 4, 1918.

Non-exclusive. Farbwerke-Hoechst Company, 122 Hudson St., New York City. Arsphenamine, Nov. 26, 1917. Neo-arsphenamine, Mar. 4, 1918. (License cancelled and license issued to H. A. Metz Laboratories, Inc., in its place.)

Non-exclusive. H. A. Metz Laboratories, Inc., 122 Hudson St., New York City. Arsphenamine, July 19, 1918. Neo-arsphenamine, July 19, 1918.

Non-exclusive. Diarsenol Company, Inc., 475 Ellicott Square, Buffalo, N. Y. (Factories in Toronto, Canada.) Arsphenamine, Jan. 12, 1918. Neo-arsphenamine, Mar. 4, 1918.

Non-exclusive. Farbwerke-Hoechst Company, 122 Hudson St., New York City. Procaine, Dec. 17, 1917. (License canceled and license issued to H. A. Metz Laboratories, Inc., in its place.)

Non-exclusive. H. A. Metz Laboratories, Inc., 122 Hudson St., New York City. Procaine, July 19, 1918.

Non-exclusive. Rector Chemical Company, Inc., 2 Rector St., New York City. Procaine, Dec. 17, 1917.

Non-exclusive. The Abbott Laboratories, 4739-57 Ravenswood Ave., Chicago, Ill. Barbitol, Dec. 17, 1917.

Non-exclusive. The Abbott Laboratories, 4739-57 Ravenswood Ave., Chicago, Ill. Procaine, Jan. 10, 1918.

Non-exclusive. The Abbott Laboratories, 4739-57 Ravenswood Ave., Chicago, Ill. Phenyl Cinchoninic Acid, Mar. 23, 1918.

Exclusive. Pacific Flush Tank Company, 4241-43 Ravenswood Ave., Chicago, Ill. Sewage Treatment Apparatus, Dec. 17, 1917. (Limhoff Tank.)

Exclusive. Lembeck, von Bernuth Company, Inc., 171 Madison Ave., New York City. Rueping Process of Treating Timber, Jan. 17, 1918.

Exclusive. Hoevel Manufacturing Corporation, 50 Church St., New York City. Sand Blast Machine, Feb. 18, 1918.

Non-exclusive. Calco Chemical Company, Inc., Bound Brook, N. J. Procaine, Feb. 18, 1918.

Non-exclusive. French Battery & Carbon Company, Madison, Wis. Depolarizer for Galvanic Cells, Feb. 18, 1918.

Non-exclusive. Antoine Chris Company, 18 Platt St., New York City. Barbitol, Mar. 11, 1918.

Non-exclusive. New Process Metals Co., Inc., 50 E. 41st St., New York City. Pyrophoric Alloy, Pyrophoric Mass, Mar. 30, 1918.

Non-exclusive. Pfanstiehl Company, Inc., North Chicago, Ill. Pyrophoric Alloy, Mar. 30, 1918.

Non-exclusive. E. I. duPont de Nemours & Co., Wilmington, Del. Anthracene, Indigo, Sulphur and Azo Dyes, Jan. 21, 1918.

Non-exclusive. Albert B. Moses, 909 Eighth Ave., Seattle, Wash. Artificial Milk, Apr. 8, 1918.

Exclusive. F. L. Smith & Co., 50 Church St., New York City. Ball-Mill, Apr. 8, 1918.

Non-exclusive. E. C. Klipstein & Sons Company, 644 Greenwich St., New York City. Hydrosulfites (Dyes), Apr. 8, 1918.

Non-exclusive. The Hagan Corporation, People's Bank Building, Fourth Ave. and Wood St., Pittsburgh, Pa. Suction Device for Dust-laden Air, May 3, 1918.

Exclusive. American Parlograph Corporation, 123 Liberty St., New York City. Talking Machine, May 7, 1918.

Non-exclusive. National Aniline & Chemical Co., Inc., 21 Burling Slip, New York City. Anthracene, Indigo, Sulphur and Azo Dyes, June 28, 1918.

Non-exclusive. Robert Reiner Importing Company, Gregory Ave. and Hackensack Plank Road, Weehawken, N. J. Embroidering Machines, July 10, 1918.

Non-exclusive. The Stearns-Roger Manufacturing Company, 1720 California St., Denver, Colo. Cellular Drying Apparatus, July 16, 1918.

Non-exclusive. Merrimac Chemical Company, 148 State St., Boston, Mass. Hydrosulfites (Dyes), July 16, 1918.

Non-exclusive. General Ceramics Company, 50 Church St., New York City. Absorption and Reaction Tower for Acids, July 19, 1918.

### TRADE-MARKS

Exclusive. Lehn & Fink, 120 William St., New York City. Pebecco (Tooth-Paste), Dec. 17, 1917.

Exclusive. The Anchor Packing Company, Lafayette Building, Philadelphia. Tauril, Feb. 49, 1918.

Non-exclusive. The Abbott Laboratories, 4739-57 Ravenswood Ave., Chicago, Ill. Veronal, Dec. 17, 1917.

## Sulphur Syndicate in Sicily

The report that accompanies the draft of the bill for granting an extension of 12 years to the syndicate interested in the sulphur production of Sicily intimates that such extension has been asked for in order to protect the principal industry of Sicily, which is confronted with greater foreign competition at a time when not only larger quantities of the product are needed for explosives but labor for working the mines is scarce. It is believed, that the intensifying of the Japanese production, the discovery of deposits in northern Africa, and the very considerable American output constitute a serious menace to the native industry. In view of the situation, therefore, it is believed that by extending for 12 years the rights of the syndicate, whose special work it is to combine and regulate the efforts of the individual producers, efficient means will be adopted for meeting the competition of the future.—*Canadian Bulletin of Trade and Commerce.*

War Department Orders New Census of Chemists

THE following open letter has been addressed to the chemists of the United States by Maj. Gen. William L. Sibert, Director of Chemical Warfare Service. The communication pertains to a new census of chemists in the United States which the War Department has found necessary in view<sup>a</sup> of the changes that have occurred since the census taken at the beginning of the war by Dr. Charles L. Parsons, Chief Chemist of the United States Bureau of Mines and Secretary of the American Chemical Society. All chemists in the United States will receive a questionnaire, which we reproduce herewith, and they should be at special pains to make a prompt return so that the War Department can be in possession of the knowledge which it now finds necessary. By returning the blank properly executed, no one binds himself in any way to any service of the Government, but he will put the War Department in possession of the necessary knowledge to enable it to turn to the chemists of the country for aid or advice.

WAR DEPARTMENT  
CHEMICAL WARFARE SERVICE  
WASHINGTON, D. C.

September 1, 1918.

TO THE CHEMISTS OF THE UNITED STATES:

This is a chemical war; therefore the War Department must have immediately available all possible information regarding chemical materials and chemical man power. Of these two essential elements chemical man power has so far received less attention. The census of American chemists made by the American Chemical Society in 1917 has been of great assistance to the War Department. Without it the present state of progress of the United States in chemical warfare would have been impossible of attainment.

However, during the same period conditions have undergone rapid and radical changes. The old census, excellent as it was, is no longer completely adequate. With the organization of the Chemical Warfare Service as an independent branch of the War Department, unifying all the elements of chemical warfare, it is obvious that the War Department must have its own set of records on a matter so vital to its own success. Moreover, these records must contain information which a short time ago was apparently of little importance. The new census must be made primarily from the viewpoint of the military status of chemists.

The importance of a prompt return of the census blank, properly filled out, by every chemist of the country cannot be overstated. American chemists are presented at this moment with one of the greatest opportunities to serve their country by the simple process of answering this questionnaire with all possible speed.

(Seal) (sgd.) WILLIAM L. SIBERT,  
Major General, U. S. A.,  
Director of Chemical Warfare Service.

QUESTIONNAIRE

Date.....  
Name .....  
          (Last)          (First)          (Middle)  
Present address .....  
Permanent address .....

I. GENERAL

1. Born (a) Date ..... (b) Place.....  
2. Age ..... 3. Place of birth (a) of father.....  
          (b) of mother ..... 4. Are you an American citizen?..... 5. If naturalized, give date ..... 6. Are you married?.....  
7. Is your wife living? ..... 8. How many peo-

ple are dependent upon you (a) wholly?.....  
(b) partially? .....

II. TRAINING

9. Give the names of the schools, colleges, universities, graduate schools, or technical schools, which you have attended, with dates of attendance, courses pursued, and degrees granted.  
.....  
Institutions      Dates      Courses pursued      Degree  
.....  
10. State any other training you have had.....  
11. State fully the courses of study in which you have specialized .....  
12. What foreign languages do you (a) speak.....  
          (b) read? ..... (c) write .....  
13. Of what technical societies are you a member?  
.....

III. PRACTICAL EXPERIENCE

14. In what foreign countries have you had experience and how much? .....  
15. How many years of continuous experience have you had? .....  
          (a) Industrial ..... (b) Teaching .....  
          (c) Other .....  
16. What experience have you had along executive and administrative lines? .....  
17. State in detail your duties in your various positions.  
.....

| From—To | Employer | Title | Nature of work | Salary (Statement optional and confidential) |
|---------|----------|-------|----------------|----------------------------------------------|
| .....   | .....    | ..... | .....          | .....                                        |

18. Publications.

| Title | Publisher | Date  |
|-------|-----------|-------|
| ..... | .....     | ..... |

19. State specifically the kind of work you do best .....  
20. In the present emergency how and where, in your opinion, could you be of most service to your country?  
.....

IV. SERVICE

21. Do you desire to enter the service of the United States at once (a) in a civilian capacity?.....  
          (b) in a military capacity? .....  
Note. If you answer this question in the affirmative, answer the rest of the questions in this section insofar as they apply to your case: Otherwise, skip to section V.  
22. What rank (or salary, if you desire a civilian appointment) would you accept? .....  
23. What has been your total military experience? .....  
24. Are you registered in the draft? .....  
25. What is your Order Number? .....  
26. What is your Serial Number? .....  
27. Have you received the draft questionnaire?.....  
28. How have you been classified?.....  
29. Give names and addresses of three or four responsible persons (not relatives) or send letters of recommendation herewith.  
.....

| Name  | Address |
|-------|---------|
| ..... | .....   |

V. MISCELLANEOUS

30. State anything else, which will aid us, or which you want us to know, which is not covered by the questions on this folder. (Answer this question last.)

# Chemical Warfare Service, National Army

## An Account of the Inception and Development of the Chemist's Part in Military Operations—Organization of the Service—Commissioned Personnel Here and Overseas

GENERAL Order No. 62 of the War Department dated June 28, 1918, will always have special significance to the chemists of the United States because therein the Secretary of War, at the direction of the President, organized the Chemical Warfare Service of the National Army.

### DEVELOPMENTS BY THE BUREAU OF MINES

The evolution of the Chemical Warfare Service is interesting because it had its inception in a branch of the Government not concerned with warfare, namely, the Bureau of Mines of the Department of the Interior. On account of the familiarity of the Bureau with noxious gases in mines, it was able to make an early start on the important work of gas warfare at a time when the War Department was deluged with other important problems. The result is that we have heard no criticism of delay in the gas warfare work such as has been directed at other branches. An important feature of the work of the Bureau was the wonderful coöperation which it secured from the leading chemists of the country who responded willingly and promptly to the call. This enabled the Bureau to turn over to the War Department a complete, well articulated organization of more than 1,800 chemists which had accomplished great things prior to being transferred.

Early in February of 1917, when war between the United States and the Central Powers seemed inevitable, the Bureau of Mines called the attention of the War Department to the already existing technical organization in the Bureau for the study of poisonous gases in mines, gas masks etc., and offered the facilities of the Bureau to the War Department for this work. A meeting was arranged between representatives of the Bureau and the War College. At this conference the War Department enthusiastically accepted the offer of the Bureau of Mines and agreed to support the work in every way possible.

The Director of the Bureau of Mines immediately directed investigations of these war problems, and until July 1, 1917, carried the work along with funds of the Bureau. The first work was done on the development of gas masks. On July 1, 1917, the staff consisted of fifty paid investigators and the work had expanded from gas-mask research to the study of poison gases and chemical warfare appliances for offensive purposes.

### COÖPERATION OF UNIVERSITIES AND RESEARCH ORGANIZATIONS

In order to enlist the coöperation of the universities and research institutions in the United States, personal visits were made to practically all of the important ones. The response was most gratifying. Up to the present time some extremely important work has come out of these universities and institutions. On April 6, 1917, the following committee on gases used

in warfare was formed by the National Research Council for the purpose of coöperating with the Bureau of Mines in connection with this work:

Van. H. Manning, Chairman, Director, U. S. Bureau of Mines.

George E. Hale, (Ex-Officio)

National Research Council, Director, Mt. Wilson Solar Observatory.

Lt. Col. R. A. Millikan, (Ex-Officio) National Research Council

..... Science and Research Division, Signal Corps.

Carl L. Alsberg, ..... Chief, Bureau of Chemistry, U. S. Department of Agriculture.

Maj. Earl J. Atkisson, ..... Corps of Engineers, U. S. A.

Lt. Col. Marston T. Bogert, ..... Chemical Service, N. A.

Lt. Col. Bradley Dewey, ..... Gas Defense Service, Surgeon General's Office.

A. H. Marks, ..... Director, Gas Service, U. S. A.

Lieut. Joseph R. Phelps, ..... P. A. Surgeon, Bureau of Medicine and Surgery, U. S. N.

Lt. Col. Earl J. W. Ragsdale, ..... Bureau of Ordnance, U. S. A.

Lieut. T. W. Wilkinson, ..... Bureau of Ordnance, U. S. N.

This committee has worked in hearty coöperation with the Bureau of Mines.

Until August, 1917, the Bureau of Mines also supervised the construction of gas masks.

On November 7, 1917, Secretary Lane appointed the following Advisory Board to the Director of the Bureau of Mines on war problems: Dr. Wm. H. Nichols, Prof. E. C. Franklin, Dr. C. L. Parsons, Mr. Wm. Hoskins, Prof. H. P. Talbot, Dr. F. P. Venable, Dr. Ira Remsen, Prof. T. W. Richards.

Since that date the Board acted in an advisory capacity to the Director on the gas work, both as individuals and as a body. The Board first met on Monday, December 17, 1917, and visited the laboratories and consulted with the research staff. They were also given a demonstration of the work in progress and full reports were made to the Board by all section chiefs. A second meeting was held on May 15 and 16, 1918, when the work was again reviewed.

It was finally decided that the Bureau of Mines would remain as a research organization, making recommendations to the Army and Navy regarding the kinds of masks and nature of gases to be used, together with their method of manufacture, and that the construction of the mask proper should be transferred to the Surgeon General's Office of the Army. The organization working for the Bureau of Mines was turned over to this department of the Army and formed the nucleus of the present huge organization working on the construction of gas masks and other appliances for gas defense.

On September 15, 1917, many of the experimenters working for the Bureau of Mines on war gas problems moved into the present headquarters of the organization at the American University, on the outskirts of Washington. The University authorities turned over the use of two large buildings at this place, rent free, but with the

proviso that some of the alterations and additions, necessary for the proper conduct of the work, would be permanent and become the property of the University after the war was over. The lease of the buildings and grounds of the University extends to a period two years from July 1, 1917, or during the war if it should extend beyond the two-year period.

#### CHEMICAL SERVICE SECTION ORGANIZED IN NATIONAL ARMY

In December, 1917, a chemical corps was established in the National Army and a part of the unit sent to France. This unit is composed largely of men trained in the Bureau of Mines' organization. In December, also, a staff of chemical engineers, working for the research organization of the Bureau of Mines, developing processes for manufacturing gases, was transferred to the Bureau of Ordnance of the War Department and formed the nucleus of the present organization, building huge plants for the manufacture of poison gases. Another organization, which had its inception under the Bureau of Mines, and has for its head a man who worked for the Bureau and received his training on noxious gas methods, is the proving-ground unit of the War Department, established at Gunpowder Neck, for actually trying out gases on an artillery scale after they have been studied by the research organization.

The personnel of the research organization also included a group working on chemical warfare devices. These substances include aeroplane gas bombs, signal lights, smoke screens to screen merchant ships from enemy submarines, gas shells, incendiary shells, gas bombs, trench projectors for firing gas bombs, flaming guns etc., and important recommendations have gone from the research organization covering such materials which have been adopted by departments of the Army and Navy interested and put into production.

In recapitulating the work of the Bureau of Mines it may be said that, by inaugurating the gas warfare program with the hearty support of the Army and Navy departments, the National Research Council, state educational, and private institutions, we are undoubtedly months ahead of where we otherwise would have been; that our soldiers have gas masks, and will have gases with which to combat the Germans; further, that the developments in gas mask manufacture by the Surgeon General's Office of the Army, in gas manufacture and gas proving-ground tests by the Bureau of Ordnance, and in the chemical warfare program of the Navy, including the use of smoke screens, shells, toxic gases etc., are the results from this experimental work.

The scientific achievements of the Bureau of Mines have been many, but the results cannot be given at this time for reasons that are obvious. It is sufficient to say that due to the energy of the research organization of the Bureau of Mines, the large scale production of toxic gases is far ahead of the supply of shells.

The Advisory Chemical Board said of the work being done by the Bureau of Mines: "The efficiency, success, fine spirit, and enthusiasm under the leadership of the Bureau of Mines is a matter upon which we wish to congratulate the Bureau, as well as upon the splendid group of unselfish, self-sacrificing men who carried on this arduous and dangerous work."

At that time before the transfer of the work the

Chemical Board added: "The organization is complex and delicate but well articulated and working with an efficiency and enthusiasm which has impressed us greatly."

#### WORK COÖRDINATED AND CONSOLIDATED BY THE PRESIDENT

As the war progressed, it became apparent that, in the interest of economy and more efficient concentration of the work, certain bureaus and agencies should be co-ordinated or consolidated. Accordingly, the experiment station at American University, which had been under the control of the Bureau of Mines, was transferred to the War Department, in which connection the following correspondence passed between Secretary of War Baker, the President and Director Manning of the Bureau.

#### WAR DEPARTMENT WASHINGTON

June 25, 1918.

My dear Mr. President:

In connection with the proposed transfer of the chemical section at American University from the Bureau of Mines to the newly constituted and consolidated Gas Service of the War Department, which you are considering, I am specially concerned to have you know how much the War Department appreciates the splendid services which have been rendered to the country and to the Army by the Department of the Interior, and especially by the Bureau of Mines under the direction of Dr. Manning. In the early days of preparation and organization, Dr. Manning's contact with scientific men throughout the country was indispensably valuable. He was able to summon from the universities and the technical laboratories of the country men of the highest quality and to inspire them with enthusiastic zeal in attacking new and difficult problems which had to be solved with the utmost speed. I do not see how the work could have been better done than he did it, and the present suggestion that the section now pass under the direction and control of the War Department grows out of the fact that the whole subject of gas warfare has assumed a fresh pressure and intensity, and the director of it must have the widest control so as to be able to use the resources at his command in the most effective way possible. The proposal does not involve the disruption of the fine group of scientific men Dr. Manning has brought together, but merely their transfer to General Sibert's direction.

Respectfully yours,  
The President. (Signed) Newton D. Baker.

THE WHITE HOUSE  
WASHINGTON

26 June, 1918

My dear Dr. Manning:

I have had before me for some days the question presented by the Secretary of War involving the transfer of the chemical section established by you at the American University from the Bureau of Mines to the newly organized Division of Gas Warfare in which the War Department is now concentrating all the various facilities for offensive and defensive gas operations. I am satisfied that a more efficient organization can be effected by having these various activities under one direction and control, and my hesitation about acting in the matter has grown only out of a reluctance to take away from the Bureau of Mines a piece of work which thus far it has so effectively performed. The Secretary of War has assured me of his own recognition of the splendid work you have been able to do, and I am taking the liberty of enclosing a letter which I have received from him, in order that you may see how fully the War Department recognizes the value of the services.

I am to-day signing the order directing the transfer. I want, however, to express to you my own appreciation of the fine and helpful piece of work which you have done, and to say that this sort of team work by the bureaus outside of the direct war-making agency

is one of the cheering and gratifying evidences of the way our official forces are inspired by the presence of a great national task.

Cordially yours,  
(Signed) Woodrow Wilson.

Dr. Van. H. Manning,  
Chief, Bureau of Mines,  
Department of the Interior.

#### FORMAL ORGANIZATION OF THE NEW SERVICE

As stated in the opening paragraph, the War Department finally ordered the organization of the Chemical Warfare Service, National Army, to remain in full force and effect during the continuation of the present war and for six months after the termination thereof.

The rank, pay, and allowances of the enlisted men of the Chemical Warfare Service, National Army, are the same as now authorized for the corresponding grades in the Corps of Engineers.

#### HEAD TO BE DIRECTOR

The head of the Chemical Warfare Service, National Army, is known as the Director of the Chemical Warfare Service, and, under the direction of the Secretary of War he is charged with the duty of operating and maintaining or supervising the operation and maintenance of all plants engaged in the investigation, manufacture, or production of toxic gases, gas-defense appliances, the filling of gas shells, and proving grounds utilized in connection therewith and the necessary research connected with gas warfare. He also exercises full, complete, and exclusive jurisdiction and control over the manufacture and production of toxic gases, gas-defense appliances, including gas-shell filling plants and proving grounds utilized in connection therewith, and all investigation and research work in connection with gas warfare.

#### FUNCTIONS OF SUBDIVISIONS OF CHEMICAL WARFARE SERVICE

The functions of the various divisions and branches are as follows:

*Overseas Division.*—This division includes personnel assigned to all divisions and corps and army headquarters in addition to those required for the supply of material in the field in France.

*Research Division.*—Charged with research into all matters pertaining to gas warfare.

*Development Division.*—For the development of material received from the Research Division to the point where it may be turned over for proving.

*Proving Division.*—Charged with the duty of proving the efficiency of material under field condition.

*Gas Defense Production Division.*—The production of material such as gas masks for use in the defensive.

*Gas Offense Production Division.*—The production of gas, containers and other material for use in offensive gas warfare.

#### FUNCTIONS OF SECTIONS IN ADMINISTRATION BUREAU

*Records.*—The recording and filing of all documents and handling mail and correspondence.

*Personnel.*—The procurement, assignment, transfer and promotion of commissioned and enlisted personnel and the listing and employment of civilians.

*Finance.*—Preparation of estimates, allotments, accounts, contracts and purchases. Handle all fiscal affairs.

*Auditing.*—The audit of all fiscal accounts.

*Transportation.*—General supervision over transportation of personnel and material.

*Property.*—To be custodian of property returns required and to have charge of all property and means of transportation connected with headquarters.

*Inspection.*—To make such general and special inspections as may be required and to suggest methods for improvement in coordination between the various divisions and branches of the Chemical Warfare Service.

*New Projects.*—For the investigation of and recommendations concerning new projects.

*Training.*—Training of personnel.

#### OFFICERS AT THE HEADS OF DIVISIONS AND SECTIONS OF THE CHEMICAL WARFARE SERVICE, N. A.

Director, Major General William L. Sibert.  
 Assistant Director, Colonel H. C. Newcomer.\*  
 Overseas Division, Colonel Raymond F. Bacon and Colonel Amos A. Fries.\*  
 Research Division, Colonel George A. Burrell.  
 Development Division, Mr. Frank M. Dorsey.  
 Proving Division, Major William S. Bacon.  
 Production Division, Gas Defense, Colonel Bradley Dewey.  
 Production Division, Gas Offense, Colonel William H. Walker.

#### OFFICE ORGANIZATION AND ADMINISTRATION

##### (1) Director, Chemical Warfare Service:

Maj. Gen. Wm. L. Sibert, U. S. A.

##### Staff:

##### Medical Officer:

Col. W. J. L. Lyster, S. C.

##### Assistant:

Captain H. C. Bradley.

##### Ordnance Officer:

Lt. Col. C. B. Thummel, O. D.

##### Assistant:

Maj. C. S. Stevenson, C. W. S.

##### Representative of British Military Mission:

Maj. J. H. Brightman.

##### (2) Assistant Director, Chemical Warfare Service:

Colonel H. C. Newcomer, C. E.

To act for the Director in his absence, in charge of all military matters and new projects. Chairman, Board of Review.

##### Military Assistants:

Maj. J. H. Walton, C. W. S.

Capt. V. L. Bohannon, C. W. S.

Capt. S. J. Delancy, C. W. S.

Capt. R. A. Baker, C. W. S.

Capt. A. Bolenbaugh, C. W. S.

First Lt. R. C. Henderson, C. W. S.

Sec. Lt. F. C. Perkins.

##### Technical Assistants:

Maj. S. A. Tucker, C. W. S.

Capt. G. W. S. Tait, C. W. S.

First Lt. L. Van Doren, C. W. S.

Mr. R. Franchot.

##### (3) Office Administration.

Major W. W. Parker, C. W. S.

In charge of files and clerical personnel, receipt and distribution of mails, collection and transmission of papers between various sections of the office, office disbursements.

##### Assistants:

First Lt. F. W. Dasher, C. W. S.

Sec. Lt. W. F. Kunkle, C. W. S.

Sec. Lt. B. W. Tipton, C. W. S.

Sec. Lt. W. D. Towler, C. W. S.

##### (4) Relations Section.

Col. M. T. Bogert, C. W. S.

In charge of relations with Universities, with industries, with the office of the Director of Purchases, Storage and Traffic, and with the War Industries Board, including its committees.

##### Assistants:

Maj. Victor Lenher, C. W. S.

Maj. W. J. Noonan, C. W. S.

Maj. Allen Rogers, C. W. S.

Maj. Samuel Avery, C. W. S.

Capt. C. V. Sheehan, C. W. S.

Capt. W. H. Hickin, C. W. S.

First Lt. H. F. Scharer, C. W. S.

Geo. S. Case.

##### (5) Personnel Section.

Major F. E. Breithut, C. W. S.

In charge of all matters pertaining to procurement and assignments of commissioned and enlisted personnel of the Chemical Warfare Service.

##### Assistants:

First Lt. G. W. Phillips, C. W. S.

First Lt. H. B. Bramlet, C. W. S.

Sec. Lt. A. E. Case, C. W. S.

##### (6) Contracts and Patents Section.

Captain W. K. Jackson, C. W. S.

In charge of Section, Member of Board of Review.

##### Assistant:

Capt. R. B. Meckley, C. W. S.

##### (7) Finance Section.

Major C. C. Coombs.

In charge of estimates, appropriations and allotments, of administrative audit of all disbursing accounts and of property. Member of Board of Review, C. W. S.

##### Assistant:

Capt. Ben Jenkins, C. W. S.

##### (8) Requirements and Progress Section.

Capt. S. M. Cadwell, C. W. S.

In charge of Section.

##### Assistant:

Sec. Lt. J. A. Schon, C. W. S.

##### (9) Confidential Information Section.

Major S. P. Mulliken, C. W. S.

In charge of Section.

##### Assistant:

Sec. Lt. H. E. Moore, C. W. S.

##### (10) Transportation Section.

Officer in charge not yet selected.

##### Assistant:

Capt. H. R. Sharkey, C. W. S.

#### COMMISSIONED PERSONNEL, CHEMICAL WARFARE SERVICE, N. A.

##### COLONELS

Raymond F. Bacon  
 Marston T. Bogert  
 George A. Burrell  
 Bradley Dewey  
 Wm. H. Walker

\*Have been nominated by the President for promotion to the rank of Brigadier General.

## Quicksilver in California

Editorial Correspondence  
FOREIGN COMPETITION

THE conference between the United States Tariff Commission and producers of quicksilver held recently in San Francisco brought out very strikingly the handicaps we are working under as compared to Spain. In the latter country, government-owned mines operated by contractors using convict labor are producing metal from orebodies worked for centuries, and still yielding large quantities of 7 per cent ore. Even considering their crude methods—it is said that a Peruvian furnace built in 1634 is still being used—their production is estimated to cost no more than \$16 per flask of 75 lb., and thus dominates the world-market. At any rate their contract with the Rothschilds' London house to sell their product at not less than £7 per flask nets them a very handsome profit at the minimum price.

In the United States, on the other hand, the deposits are small, irregular, and normally of low grade. While there are some mines which have never entirely shut down since their discovery about 1850, and some containing relatively rich ore, the industry steadily declined for several years immediately preceding the war. At that time a sudden inflation and violent fluctuations resulted in the price finally being fixed at \$105, an increase of 150 per cent over the normal. This induced the opening of many prospects, but 90 per cent of the increased output still comes from companies operating four years ago. However, the grade of ore is very low, the New Idria in San Benito County, California, which is America's greatest quicksilver mine, now treating ore containing but  $6\frac{1}{2}$  lb. mercury per ton. The Sulphur Bank Association in Lake County, California, is steam-shovelling old dumps and surface workings containing no more than  $1\frac{1}{2}$  lb. metal per ton, which may be considered the present minimum limit for profitable extraction. Generally speaking, the average American ore mined today contains about 5 lb. of quicksilver per ton, that is to say, a metal content of 0.25 per cent, as compared to 0.85 per cent mined in Austria, 1 per cent in Italy and 7 per cent in Spain.

### CONCENTRATION AT NEW IDRIA

Such lean ore seems to offer a promising field for modern concentration methods. Indeed, many miners and metallurgists have attacked the problem recently despite the dictum of the older operators that "you can't concentrate quicksilver ores." The sulphide cinnabar has a specific gravity of about 8.0 as compared to that of 4.2 of the easily-treated calcopryrite. It has been demonstrated that if the cinnabar is massive and crystalline, and stage-crushing be carefully done to avoid sliming the very friable mineral, very good recoveries (up to 86 per cent) may be obtained on tables working with classified and deslimed sands. On the other hand, if the ore has been ground so as to slime the cinnabar, the values float in suspension like "paint," and are not recoverable on table, vanner, or flotation machine. Under such conditions the recovery may easily fall to 60 per cent or even lower.

Thus a well equipped and carefully controlled operation is essential to success, and it is not surprising that

the many mills which were hurriedly installed a couple of years ago at the height of the fashion are generally abandoned. Two, which are probably the largest in California, are still in operation—one at the New Idria treating 300 tons daily, and another of 350-ton capacity treating Sulphur Bank ores. According to Mr. H. W. Gould, general superintendent of these properties, even these mills are economically unjustified, and their closure is imminent. A brief description of the flow sheet at New Idria, however, may be worth while (Fig. 1).

The ores are dumped over a grizzly into the mill bins, from whence they are drawn on a belt conveyor to a  $\frac{3}{4}$ -in. trommel. The oversize enters a  $7 \times 6$  ft. Allis-Chalmers granulator ball mill with a screen discharge, the ground material entering a 6-cell Richards hydraulic classifier. Each cell of this classifier supplies feed for

FIG. 1.—FLOW SHEET OF NEW IDRIA MILL.

one of a battery of six double-deck Deister sand tables. The table tailings, together with the considerable quantity of valuable slimes, go to the dump; the concentrates, containing perhaps 70 per cent of the values, to bins; while all middlings are returned by elevator to the head of the system for regrinding and retreatment.

The conditions at Sulphur Bank are quite unique. Here, as already noted, a steam shovel loads motor trucks with ore from old mine dumps and upper workings averaging only  $1\frac{1}{2}$  lb. of mercury per ton. These trucks dump their load on a  $1\frac{1}{2}$ -in. grizzly—all oversize is wasted, as the bulk of the values is in the fines. The undersize is drawn from a storage bin by a mechanical feeder into a long trommel with various openings ranging from 1 in. to about 20 mesh. All portions  $\frac{3}{4}$  in. and coarser are separately stored for future rehandling, while the material from  $\frac{3}{4}$  in. to 10 mesh is roughly concentrated in a single compartment jig. Material finer than 10 mesh is classified, the sands being con-

centrated in Deister-Overstrom tables and the slimes on Frue vanners. The total recovery in this mill, owing to the peculiar conditions surrounding its operation, possibly does not exceed 30 per cent; all slimes and sand-tailings are carefully stored, however, for future treatment. In this manner the concentrator acts as a device to skim the cream from the feed—to get some concentrates ranging in richness from 3 to 50 per cent for quick recovery of the metal at a period of high price and insistent demand.

#### ECONOMICS OF CONCENTRATION

This probably is the present function of concentration of quicksilver ores; to get a little rich material to mix with the coarser low-grade furnace-feed so as to increase the mercury output of present furnace and condenser equipment. The calcining of the ores is simple, efficient and cheap, costing not more than 75 cents per ton, and it is doubtful if the cost of modern concentration in small isolated plants can approach that of furnacing, even considering the much lower fixed investment in the mill per ton-day capacity. Added to this is the variation in nature of the different small ore deposits, each requiring close study to effect good recoveries—one will slime excessively during crushing, another may refuse to act satisfactorily in a flotation machine, another may be very costly to grind. These difficulties have converted many milling enthusiasts to the attitude of the "old timer." In other words, decreased costs may better be expected through increased efficiency in mining, which is three times as expensive as the subsequent metallurgical treatment.

A possible field for concentration is in connection with the development of a new prospect. Here the mineral indications might not warrant the building of an expensive furnace plant—indeed, the operators might readily lack the required capital—but a small crushing and table or flotation plant could easily be installed which would produce a concentrate worthy of shipment. As the orebody is developed, the returns from the ore will provide the funds for a local calciner, when the old mill can be discontinued and the raw ore together with the mill slimes and tailings smelted. Certain peculiar types of ore may be developed which are evidently concentrating propositions par excellence. As an example, the Black Butte Mercury Mining Company in Lane County, Oregon, has a peculiar soft ore which crushes very easily and floats very well, reducing the costs to a minimum.

#### MERCURY FURNACES

Concentrates, or very rich, fine ores in small quantity, are best treated in retorts. In its most simple form, such a furnace consists of a horizontal row of up to a dozen 12-in. iron pipes, closed at the rear with a tight removable plug, and the front fitted into a condenser, which may be merely a water jacketed 3-in. pipe, 7 to 10 ft. long. The muffles themselves may be entirely bricked in, and heated by flues leading underneath and above, leading from a wood-burning fire box or oil-flame at one end. The retorts have a small capacity, handling perhaps 150 lb. of rich ore or 75 lb. of concentrates (plus the necessary lime) per shift. Condensation of fume is easiest, since only in this type is the volatile

mercury uncontaminated by the products of combustion.

Coarse low grade ore, 3 to 9-in. lumps, on the other hand, has long been treated in vertical shafts resembling lime kilns of round or oblong cross-section. In order to prevent top-losses, a bell-charging device is desirable, the vapors being drawn off at about 200 deg. C. through down-comers just below, or through multiple openings in the shaft walls. The calcined ore is removed from the bottom at a temperature around 600 deg. C. and calcination is effected by fire-boxes located just above. These furnaces are very economical of labor and fuel, requiring one cord of wood for 20 tons of ore, while a rectangular oil-burning shaft at New Idria has been treating from 25,000 to 30,000 tons of ore per year at a total cost of somewhat less than 50 cents per ton. Since the "furnace gets it all" in the words of the operators, one readily sees what stiff competition any scheme of concentration would encounter in these calciners.

#### SCOTT FURNACE

Perhaps 75 per cent of the American production in recent years has been obtained from finer ore treated in the Scott furnace, an improved Hasenclever furnace developed by Hüttner, Scott and Randol at New Almaden in 1875. As is perhaps well known, the Scott furnace is a rectangular block of brickwork with combustion chamber at one end and a fume chamber covering the end opposite. Between the two and leading from front to back are a series of parallel vertical slots, perhaps 20 in. wide, open from the top, where ore is charged, to the bottom where it is withdrawn. In its passage through the furnace, however, the ore rests on 30 or more deflecting shelves (Fig. 2) inclined downward at 45 degrees alternately from right and left wall,

FIG. 2.—CROSS-SECTION SHOWING CONSTRUCTION IN SCOTT FURNACE

made of a line of 15 x 3 x 36-in. tiles. The tiles are set so that a slot of about 5 in. is left between the lower edge and upper surface of each succeeding pair of tiles, which slot is kept sealed by the descending ore stream. Furnace gases use the space between the top of the ore

and the bottom of the tile immediately above as a flue, heating the thin bed of slowly descending ore and volatilizing its mercury content.

The capacity of the furnace is evidently a function of the length and the output of the mine it serves. It is commonly built of 75-ton capacity, with locally-made red brick for condensers and furnace masonry, and its cost is commonly quoted at \$1000 per ton-day capacity. Dry granular ore fed to the top remains in the furnace about 24 hours before being drawn off below, during which time its temperature progressively increases to perhaps 1000 deg. C. Naturally, proper firing is an essential, 5 to 6 gallons of fuel oil or 0.03 to 0.05 cords of wood per ton of ore being required. This could be somewhat reduced, and an increased efficiency in the condensation system attained by more careful firing and narrow regulations of excess air of combustion. As it is, the cost of treatment is quite low—70 to 80 cents per ton, exclusive of interest and repairs, which latter are quite extensive at intervals of perhaps three years.

#### FURNACE RECOVERY

Metallurgically, the Scott furnace is a very efficient machine. As determined by Dr. L. H. Duschak of the Bureau of Mines, the top losses are extremely low, owing to the effective seal made by the fine ore. In one case it amounted to about  $\frac{1}{2}$  lb. of mercury per day in a 50-ton furnace. The calcined ore contains only a negligible amount of values; under good operation it assays as low as 0.02 per cent, while ordinary care will produce a cinder with 0.07 per cent Hg. Losses of metal as uncondensed vapor escaping up the stack have generally been considered most serious, but Dr. Duschak shows that if 75 tons of 0.7 per cent ore is burned with the usual excess air of combustion, and the resulting gases cooled to 40 deg. C., the uncondensed vapor will amount to only  $4\frac{1}{2}$  lb. of mercury. The stack losses of fine fume are practically zero if the gases are cooled with a water spray; this water of condensation in turn dissolves some acid but very little metal, and its floating content of floured mercury can be reduced by proper settlement or recovered during re-use. Altogether, the furnace extraction under good management may very readily exceed 90 per cent. As a matter of fact, average practice bottles no more than 75 per cent of the mercury in the ore. (Mercury "hangs up" in the condenser system in excessive measure—at one well-conducted plant a monthly metallurgical balance showed recoveries ranging from 60 to 130 per cent.) Definite figures are difficult, if not impossible, to obtain, for few plants make any serious effort to sample and weigh the ore as it is fed, nor account for any metal in process except that actually shipped. A leaky system operating at slightly greater than atmospheric pressure may lose much vapor at the joints. This is entirely overcome, however, by maintaining a slight suction at all times by stack or fan draft.

The most important apparent loss is in the absorption of metal by the brickwork and foundation. This is very difficult to estimate and is not considered an ultimate loss as the mercury so absorbed is largely recovered when the plant is dismantled. It is an important factor in a new plant, since, by tying up a

considerable amount of metal, it has the effect of increasing the capital investment required at the commencement of operations. In periods of abnormal prices, furnaces have been frequently dismantled to recover this mercury—a practice not consistent with good metallurgy, but often financially advisable. As much as 1000 flasks is reported to have been produced by the tearing down of a single furnace and condenser system, and old furnace sites have been excavated to a depth of 35 ft. before reaching earth not carrying visible beads of "quick."

#### MECHANICAL ROASTERS

Metallurgically the process of extracting mercury from the ore is quite similar to the roasting process practiced in large measure elsewhere, the reaction induced by extraneous heat,

taking place above the boiling point of mercury (360 deg. C.). It is only natural that roasters of the Herre-

FIG. 3.—ROTARY QUICKSILVER FURNACE AT NEW IDRIA

shoff type so successful elsewhere should be tried, as has been done at New Almaden, where one treats 45 tons of  $\frac{3}{8}$ -in. ore daily.<sup>1</sup> The sulphur in the ore is insufficient to provide much of the required heat, so extra fire boxes are installed. A high consumption of fuel (8 gal. oil per ton) is required, owing to the radiation through the relatively thin walls, and an excessively dusty gas is made. This is treated while at 600 deg. F. in a Cottrell electrostatic precipitator, the gas then cooled and the mercury condensed in ordinary chambers, the cold effluent of which passes through a second cold Cottrell treater, which actually collects a vanishingly small amount of mercuric mist. At this plant a very large Scott furnace has recently been installed of 90 tons daily capacity, which produces a clean vapor with  $\frac{2}{3}$  the fuel consumption—this of course being a simpler and more desirable combination than the mechanical roaster.

H. W. Gould of the New Idria Company has recently tested a 4 x 50-ft. rotary furnace with very promising results, so much so that a second 5 x 56-ft. furnace was later installed, and four more are under order. The fur-

<sup>1</sup>See W. H. Landers, *E. & M. J.*, Oct. 7, 1916, p. 631.

nace, which is shown in Fig. 3, is like an ordinary cement kiln, receiving ore at the upper end, coned slightly to keep the discharge free of material. The furnace is fired not enough so that the entire lining is at a temperature of more than 350 deg. C., thus preventing any metal absorption. The first furnace treated 95 tons of 14-in. ore daily, or 70 tons of 1½-in. ore: probably ¾ to

FIG. 4—WOODEN CONDENSER TANKS AT NEW IDRIA

1-in. size will be most desirable, the ore remaining in the furnace from 15 to 30 min., depending upon the volume of the ore stream, and leaving at a temperature of over 900 deg. C. in a mercury-free condition. The further advantages of this rotary furnace are its low first cost, being one-quarter to one-half that of older types, and its low consumption of fuel, while the automatic feed and discharge cuts attendance charges to a minimum.

Condensation problems have been attacked at this plant with notable success, as well. The hot dusty gases first enter a brick dust chamber of considerable volume at the end of the furnace, where the solid particles largely settle. The gases, still at 300 deg. C. or more, then pass through a flue made of 18-in. sewer tile into the first wooden tank shown in Fig. 4, 20 ft. in diameter and 30 ft. high. Several sections of this tile flue have side outlets, through which a tile bend enters, open to the air at the outer end and the inner turned in the direction of the gas stream (Fig. 5). Fixed at the end of the tile bend is a water spray which not only cools the hot gases by its evaporation, but sucks outside air into the flue by injector action. The result is that the hot dry gas leaving the brick chamber enters the wooden condenser saturated with water vapor and at about 80 deg. C. During the passage through the three condensers shown in Fig. 4, the gases further cool to 40 or 50 deg. C., depositing practically all of their mercury and much of their water—the bulk collecting in the first tank. The condensers themselves are placed several feet above a concrete basin, and the mercury and water withdrawn periodically through valve-controlled drain pipes. Very little soot is formed in this installation, thus warranting the discontinuance of their rather elaborate soot-mill.

The advantages of this condenser system are obvious. Wooden tanks are very easily and cheaply built and kept air tight, metal absorption is very low, clean-ups may be readily effected by merely hosing down the walls, the metal is withdrawn without the dangerous necessity of entering the condensers, and there are no dead spaces for sulphuric acid and mercury gases to eddy about and combine. Mr. Gould and his associates are

to be congratulated on this very evident advance in the art of getting quicksilver.

The expected consumption of quicksilver in the United States during the year 1918 was estimated in April by Mr. F. L. Ransome, of the U. S. Geological Survey, as follows:

|                                                           | Flasks |
|-----------------------------------------------------------|--------|
| Drugs and chemicals, largely calomel and dental amalgams  | 12,180 |
| Fulminate for detonators                                  | 12,218 |
| Antifouling ship-paint (red oxide)                        | 2,905  |
| Vermillion (mercuric sulphide)                            | 1,900  |
| Electrical uses in rectifiers and vapor lamps             | 2,687  |
| Felt making (mercuric nitrate)                            | 1,800  |
| Amalgamation of gold and silver ores                      | 800    |
| Thermometric, barometric and other scientific instruments | 676    |
| Boiler feed-water treating compounds                      | 700    |
| Cosmetics                                                 | 300    |
| Total                                                     | 36,166 |

The mines of the United States could probably easily supply this amount if our exports were discontinued, since the production in 1917 amounted to 36,351 flasks. Great activity in production is necessary, however, since some of the manufacturers of fulminates have but recently received largely increased estimates of requirements for the army and navy, one estimate demanding more mercury than the entire total above given.

In case of an acute shortage, many of the uses could be considerably curtailed, either by non-supply or by substitution. For instance, cosmetics, water treating compounds, felt making, and vermilion could largely be foregone, temporarily. Miscellaneous chemicals could be sharply curtailed, as well. Substitutes for fulminate, were largely imported from Germany prior to the war and were used in blasting caps, replacing a large amount of fulminate when mercury was at prices above \$40. These imported compounds are now about

FIG. 5.—TILE FLUE FOR COOLING MERCURY VAPOR

exhausted, and their methods of manufacture are unknown—American-made substitutes require fulminate to detonate them, and may cut down the mercury consumption about 75 per cent. It is understood, however, that at present prices of substitutes it is cheaper to use pure fulminate when mercury is at \$75 and probably even at the present \$105. As to their reliability of operation, it suffices to say that the ordnance departments of the allied governments will not accept substitutes in caps or detonators. This confines their use to blasting caps for mining and excavation and in the making of sporting goods. In the latter case a misfire is not so vital, while in blasting the insertion of two caps in every important shot will insure 100 per cent operation at a small relative increase in cost.

# The Metallography and Heat Treatment of Metals Used in Aëroplane Construction—III

Investigation of Parts Made from Chrome-Vanadium, Nickel, Chromium and Tungsten Steels—Causes of Failure in Piston Pins, Axles and Bolts—Physical Properties of Raw and Treated Materials

By F. GROTTES

Chief Metallurgist, Curtiss Aëroplane and Motor Corporation

## CHROME-VANADIUM STEEL

**P**ISTON pins and connecting rods are made from chrome-vanadium steel. The piston pins have a slightly higher carbon content than the connecting rods. This material, when properly heat-treated, has a very fine structure and is very tough and strong.

The defects found are manganese sulphide, slag and seams.

Connecting rod analysis: C, 0.35; Mn, 0.78; S, 0.027; P, 0.025; Cr, 0.94; V, 0.17.

Physical properties of raw stock.

|                                |         |
|--------------------------------|---------|
| Ultimate tensile strength, lb. | 136,700 |
| Yield point, lb.               | 85,200  |
| Elongation, per cent.          | 15.6    |
| Reduction, per cent.           | 45.5    |

| Scleroscope                    | 42      |

Double quenched 1700 deg. and 1600 deg. in oil; drawn at 1200 deg.

|                                |         |
|--------------------------------|---------|
| Ultimate tensile strength, lb. | 145,000 |
| Yield point, lb.               | 135,000 |
| Elongation, per cent.          | 18      |
| Reduction, per cent.           | 62      |
| Brinell                        | 300     |
| Scleroscope                    | 48      |

Piston pins are drawn at 1000 deg. and it is essential that the greatest possible care and supervision be given them in order to get satisfactory results. Defects have been found in pins that were thought to be seams but were in reality due to faulty heat-treating. In quenching, the pins should be dropped in vertically and not tossed in indiscriminately. Oil is nearly always used as a quenching medium but hot water can be used with good results. This is similar to the conditions found under chrome-nickel piston pins where the hardening cracks occurred.

## PISTON PIN INVESTIGATION

These pins are made from chrome-vanadium steel and have an analysis of C, 0.46; Mn, 0.68; S, 0.028; P, 0.032; Cr, 1.12; V, 0.14. On being machined small hair lines appeared that resembled a hardening crack; also it was observed that some pins were very soft.

The object of the investigation was to determine the cause of the cracks which in some cases extended from end to end, and also to investigate the heat treatment.

**Procedure:** The 50 pins submitted, which were supposed to have been heat-treated, were scleroscoped and showed a hardness of 20 to 26.

Fifteen of the pins taken as representatives of the lot were heated up to 1760 deg., held 10 minutes and quenched in oil. After they had cooled, they were re-

quenched in oil at a temperature of 1600 deg., the hardness averaging 58 after the second quench.

Five of the 15 pins were drawn at 800 deg., air-cooled and showed a hardness of 53 to 55. Another 5 were drawn at 900 deg., air-cooled and showed a hardness of 49 to 52. The remaining 5 were drawn at 1000 deg., air-cooled and showed a hardness of 44 to 47.

A section taken at the crack was polished and photographed at a magnification of 100. The result is shown in Fig. 62. Another section was polished and etched

PLATE 5.—PROPERTIES OF CHROME VANADIUM STEEL

with alcoholic nitric solution, with the result shown in Fig. 63.

**Summary:** These pins when heat-treated properly give a hardness of about 50 to 55; so the treatment of these pins originally was incorrect (drawn too high). The cracks found were seams containing oxide, as shown in Fig. 62.

Fig. 63 shows how the steel was decarbonized near the seam. The structure shows ferrite with sorbite, indicating that the draw was somewhat too high, probably about 1250 deg. Fahrenheit.

FIGS. 57-63

Figs. 57-61—Chrome Vanadium Steel. Analysis: C, 0.35 per cent; Mn, 0.78; S, 0.027; P, 0.025; Cr, 0.94; V, 0.17. Etched with picric acid; magnification, x 100. Fig. 57—Quenched; 58—quenched and drawn at 800 deg.; 59—quenched and drawn at 1000 deg.; 60—quenched and drawn at 1200 deg.; 61—raw stock; 62—63—Cracks in piston pins; x 100.

### NICKEL STEEL

This is a typical pearlitic steel and one of the most important in aeroplane construction, as the nickel going into solution into the ferrite increases its strength, elastic limit and hardness, which in turn makes a stronger and harder pearlite, therefore a better steel than an equivalent carbon steel. It will stand lots of cold working in the annealed state. It is used for bolts, nuts and parts subject to shock.

The average composition is C, 0.32; Mn, 0.50; S, 0.035; P, 0.0173; Ni, 3.74.

The critical points are slightly lower than those of a same percentage carbon steel, the heating point being about 1325 deg. F. and the cooling about 1175 deg. F.

It is very susceptible to oxidation and should be

placed in boxes or handled in a reducing or neutral atmosphere when being heat treated.

#### Raw stock physical properties:

|                               |         |
|-------------------------------|---------|
| Ultimate tensile strength, lb | 112,200 |
| Yield point, lb               | 97,200  |
| Reduction, per cent           | 49.9    |
| Brinell                       | 217     |
| Scleroscope                   | 40      |

Quenched in oil at 1500 deg. F. and drawn at 1000 deg. F.:

|                               |         |
|-------------------------------|---------|
| Ultimate tensile strength, lb | 120,000 |
| Yield point, lb               | 100,000 |
| Reduction, per cent           | 65      |
| Elongation, per cent          | 20      |
| Brinell                       | 230     |
| Scleroscope                   | 38      |

The most common defects found in this stock are pipes and slag inclusions. More pipes are found in this material than in any other. Owing to the peculiar frac-

FIGS. 64-75.

FIGS. 82-88.

Figs. 82-85—Vanadium Steel. Analysis: C, 0.22; Mn, 0.72; S, 0.039; P, 0.04; V, 0.12. Etched with picric acid; magnification, x 100. Fig. 82—Quenched stock; 83—quenched and drawn at 800 deg.; 84—quenched and drawn at 1000 deg.; 85—annealed. Figs. 86-88—Tungsten Steel. Analysis: C, 0.47; Mn, 0.38; S, 0.025; P, 0.01; Cr, 3.15; V, 0.72; W, 15.55. Etched with picric acid; magnification, x 100. Fig. 86—Quenched in oil; 87—heated to 1950 deg. and cooled in air; 88—quenched and drawn at 1400 deg.

object of the investigation was to determine the cause of the brittleness and also to investigate the lines.

A section was taken and examined carefully, then polished, etched and photographed. This section was scleroscoped and brinelled, then drawn at a temperature of 500 deg.

Fig. 70 shows the structure and nature of the axle. Fig. 71 shows the peculiar surface lines that occurred along the length of the axle. The material as it was, scleroscoped 65 and brinelled 495; on being drawn at 500 deg. for 30 minutes, it scleroscoped 55-56 and brinelled 395-400 (See Fig. 72).

**Summary:** The investigation shows that this material was merely quenched and never drawn at all. The surface lines were folds. In the forging or rolling

of the steel, thin plates or sheets of oxide were folded in. Material that has as many folds as this should be rejected as it will certainly fail when subjected to stress or vibration. A flaw of this kind can never be improved and there is no question but that it will grow.

#### BOLT INVESTIGATION

Two parts fabricated from nickel-steel were investigated because one failed in service. A section of the one that had not had the strain of the other was polished, and photographed at a magnification of 100. It is shown in Fig 73.

This is a typical sand split and is made up principally from manganese sulphide. The sulphur prints show an abundance of sulphur. Bars that have in-

clusions of this size should be rejected, as they are unfit for use.

#### OVERHEATED BOLT

A base bolt used for holding the engine in place, on shearing in two was investigated. A section on being polished, etched with picric acid and photographed at a magnification of 100 showed as in Fig. 74. This bolt was overheated at a temperature probably of 1850 to 1900 deg. As it is, it is very soft and has no strength. Cases like this occur when couples do not register properly or when workmen sleep on the job.

Material shown in Fig. 74 was heat-treated by heating to 1525 deg., holding for ten minutes and quenching in oil, then drawing at 1000 deg. and cooling in air. It is interesting to observe in Fig. 75 that this material has been refined very nicely. Carbon steels of the same carbon content as this nickel steel when handled at the same temperatures failed to give satisfactory results.

#### CHROMIUM STEEL

This steel is particularly of value because of its non-corrosive properties. This particular steel having an analysis of 0.24 C, 0.36 Mn, 0.013 S, 0.020 P, 10.44 Cr and 0.30 V, was subjected to solutions of water, 10 per cent salt, 10 per cent sodium hydroxide and 1 per cent sulphuric acid for five days. There was no effect except

PLATE 7.—PROPERTIES OF CHROMIUM STEEL

in the case of the acid which darkened the surface of the specimen slightly.

Specimens on being quenched in oil showed that a temperature of 1800-1825 deg. gave the best results:

| Temperature | Brinell | Scleroscope |
|-------------|---------|-------------|
| 1,400       | 179     | 34          |
| 1,450       | 187     | 35          |
| 1,500       | 351     | 53          |
| 1,550       | 364     | 55          |
| 1,600       | 387     | 57          |
| 1,650       | 418     | 61          |
| 1,700       | 477     | 60          |

PLATE 8.—PROPERTIES OF TUNGSTEN STEEL

Physical properties when quenched at 1800-1825 deg. in oil and drawn at 850 deg.:

|                                |         |
|--------------------------------|---------|
| Ultimate tensile strength, lb. | 225,000 |
| Yield point, lb.               | 220,000 |
| Elongation, per cent.          | 14      |
| Reduction, per cent.           | 50      |
| Brinell.                       | 430     |
| Scleroscope                    | 72      |

#### VANADIUM STEEL

This steel is especially good for sheet steel that has to be fabricated into parts that are punched, e.g., machine-gun mounts, etc. It is very tough and has much better physical properties than ordinary sheet steel.

Chemical analysis: 0.22 C, 0.72 Mn, 0.039 S, 0.040 P, 0.12 V.

Quenched in oil, it gave the following results:

|                                | 1500 Deg. | 1600 Deg. | 1700 Deg. |
|--------------------------------|-----------|-----------|-----------|
| Ultimate tensile strength, lb. | 139,000   | 195,300   | 202,000   |
| Yield point, lb.               | 113,000   | 168,000   | 172,100   |
| Elongation, per cent.          | 3.00      | 4.5       | 6.75      |
| Scleroscope                    | 44        | 55        | 58        |

Quenched in oil at 1700 deg. and drawn:

|                                | 1000 Deg. | 1100 Deg. | 1200 Deg. | 1300 Deg. | 1400 Deg. |
|--------------------------------|-----------|-----------|-----------|-----------|-----------|
| Ultimate tensile strength, lb. | 124,000   | 118,600   | 106,000   | 88,000    | 75,600    |
| Yield point, lb.               | 114,700   | 105,400   | 98,000    | 76,400    | 60,800    |
| Elongation, per cent.          | 14        | 15        | 15        | 18        | 20        |
| Scleroscope                    | 38        | 37        | 35        | 32        | 28        |

#### TUNGSTEN STEEL

Tungsten steel is used for high-speed cutting tools and exhaust valves. It requires a very high temperature to harden it successfully. An interesting property

is that it may be heated to a dull red and still retain its cutting properties.

Physical properties of raw stock:

|                               |         |
|-------------------------------|---------|
| Ultimate tensile strength, lb | 110,000 |
| Yield point, lb               | 84,800  |
| Reduction, per cent           | 54.00   |
| Elongation, per cent          | 24.00   |
| Brinell                       | 207     |
| Scleroscope                   | 35      |

(To be continued)

Chemical analysis: 0.47 C, 0.38 Mn, 0.025 S, 0.01 P, 3.15 Cr, 0.72 V, 15.55 W.

Quenched at 1950 deg. in oil and drawn at 400 deg.:

|                               |         |
|-------------------------------|---------|
| Ultimate tensile strength, lb | 248,000 |
| Yield point, lb               | 225,000 |
| Reduction, per cent           | 43      |
| Elongation, per cent          | 6       |
| Brinell                       | 520     |
| Scleroscope                   | 64      |

## The Magnetic Permeability of Steel

Permeametric Measurement of Magnet Steels Used for Electrical Machinery—Value of Hysteresis Data in Standardizing and Inspecting Steel Tools—Commercial Permeameters

By FRANK P. FAHY

PERMEAMETERS are employed in the determination of the magnetic properties of materials. These properties may be considered to be defined by the normal induction and hysteresis data.

A normal induction curve, or the ascending magnetization curve,  $OAC$  in Fig. 1, is the curve determined by the plotting of points representing the values of normal induction (magnetization) reached under various magnetizing forces when the material under examination has previously been demagnetized. Magnetic induction, or flux density, is represented by the symbol  $B$ , and magnetizing force by the symbol  $H$ . The quotient  $B/H$  for any point on the normal induction curve gives the permeability or magnetic conductivity for the material under the conditions represented by that point.

If after magnetizing a specimen of material to a given value of induction the magnetizing force is decreased, the induction observed for the new value of magnetizing force does not correspond to the value previously obtained in the measurement of normal induction, but has a higher value. In other words, the descending curve of magnetization,  $CDEFG$ , shows a distinct lagging in the fall of induction with respect to magnetizing force. To finally reduce the induction to zero requires the application of a magnetizing force in the opposite direction to that originally imposed. To this lagging effect has been given the name hysteresis. The amount of lag varies with the nature of the material and the degree to which it has been previously magnetized.

The information to be derived from the normal induction and hysteresis data is of the first importance in the selection of material intended for use in the construction of electrical machinery or apparatus which depends for its efficient operation upon the magnetic characteristics of some component part. Sometimes material of high permeability and low hysteresis is required, as in generators, motors and transformers. On the other hand permanent magnet material must have opposite characteristics to the above.

The question of the magnetic characteristics of iron and steel, and necessarily the methods of measuring such characteristics, is one of importance to metallurgical chemists. The signal improvement in recent years in the magnetic quality of transformer steels is the happy result of skilled chemical and metallurgical treat-

ment. The more recent work of Yensen<sup>1</sup> on electrolytic iron melted in vacuo, which when translated into practice will mean greatly increased operating efficiency in many forms of electrical apparatus, is another case in point. The magnetic characteristics of this exceptional

FIG. 1.—NORMAL INDUCTION CURVE

material may be modified by variations in chemical content so as to suit the material to special operating conditions.

At the present time particular attention is being given to research work on permanent magnet material. There are several reasons for this. First and foremost is the enormously increased demand for magnet steels for magneto construction. Again, a short time ago the scarcity and price of tungsten led to further investigation in the matter of substituting chrome as the preponderating alloying element. Chrome magnet steels were not unknown, but the action of tungsten being apparently more favorable to the attainment of the desired magnetic characteristics, the use of such steels was limited. While magnet steels of good characteristics are readily procurable today, it is a fact that develop-

<sup>1</sup>"Magnetic and Other Properties of Electrolytic Iron Melted in Vacuo," Trygve D. Yensen, Engineering Experiment Station, University of Illinois, Bulletins Nos. 72 and 77.

ment work along this line has lagged to such a degree that there is room for very considerable improvement. Some of the more recently developed steels have yet to be subjected to tests in apparatus known to be capable of giving accurate test results before the claim made for them may be accepted.

The present interest displayed in the subject makes it desirable to explain briefly here the meaning of some of the criteria which are used to characterize permanent magnet steels. Material intended for this purpose is practically always used in the heat-treated condition; i.e., the raw stock is hardened in oil or water from above the critical range and may or may not be drawn thereafter. Sometimes the steel, after hardening, is subjected to an ageing process, thermal in nature, which consists in heating it several times to about 100 deg. C., each heating being followed by immersion in cold water. Another ageing process subjects the material to the effects of mechanical jarring. Both of these ageing processes are intended to mature the material by effecting promptly a large part of the change which would occur in the course of time due to the secular softening of the material. This maturing or ageing is of special importance where constancy of the original properties of the magnet must be maintained.

#### THE HYSTERESIS CONSTANTS: REMNANT INDUCTION AND COERCIVE FORCE

If the magnetizing force is removed, after the material is magnetized to a high degree as  $C$ , Fig. 1, under conditions where the magnetic circuit is entirely closed upon itself, the induction falls to the value corresponding to the point  $E$ . The value of this induction, shown by the ordinate  $OE$  is known as the residual induction. If the magnetizing force is then reversed in direction and gradually increased the induction is reduced finally to zero at a value of reversed magnetizing force shown by the abscissa  $OG$ . This reversed magnetizing force is known as coercive force. Both the residual induction and coercive force must be known to properly determine the quality of material intended for use in permanent magnets, and both should be as high as possible in value. Collectively these two quantities are known as the hysteresis constants.

While the standard tests of permanent magnet material are made under conditions where the magnetic circuit is closed upon itself, the influence of joints in this circuit, being corrected for, magnets themselves are usually employed under circumstances where the magnetic circuit is open. An instance may be found in the case of a magneto, where the armature revolves between the open ends or poles of the magnet, which in this case is horse-shoe in shape. Here the circuit is made up of the magnet, two air gaps and the armature core. The open circuit modifies in an important manner the induction above designated as the residual induction, for the reason that the poles of the magnet exert a demagnetizing influence on the magnet itself which reduces the induction. We have then to consider a new term, namely, remanent induction. Remanent induction is to the open magnetic circuit what residual induction is to the closed magnetic circuit.

It is the remanent induction which serves the immediate useful purpose in a magnet, as it determines the strength of the magnet under the conditions in which it

is to be used. The loss of induction due to the open circuit, that is, the difference between the residual induction and remanent induction, depends upon the form of the magnet, the value of the residual induction and the value of the coercive force. In Fig. 2 are plotted curves for magnet steel material Nos. 1 and 2 which

FIG. 2.—RESIDUAL INDUCTION AND COERCIVE FORCE

will assist in making this clear. The curve  $CEG$  for material No. 1 shows a residual induction equal to  $OE$  and a coercive force equal to  $OG$ ; the curve  $C'E'G'$  for material No. 2 shows a residual induction equal to  $OE'$  and a coercive force equal to  $OG'$ .

The self-demagnetizing influence may be expressed by means of a coefficient or factor which in some cases can be calculated and is always subject to close experimental determination. If we assume magnets of the same size and shape made up of materials Nos. 1 and 2, then since the materials have the same form and the same residual induction the demagnetizing coefficients will be similar. The action of this coefficient may be shown graphically by drawing the line  $OL$ , making an angle  $\alpha$  so that tangent  $a$  represents the demagnetizing coefficient. The intersection of the line  $OL$  with the curves  $CEG$  and  $C'E'G'$  determines the remanent inductions of the two magnets. From Fig. 2 it will be seen that the remanent induction of the magnet made from material No. 1 is equal to  $OE_1$ , while that made from material No. 2 is greater and is equal to  $OE_2$ . It is obvious that the value of the coercive force is the determining factor in limiting the loss of induction.

Coercive force, besides being of value in helping to overcome the demagnetizing influence, is also of assistance in counteracting the effects of severe vibration which magnets are frequently subjected to under the conditions of use. The practical importance of high coercive force therefore lies not only in its action in cutting down the loss of induction due to the demagnetizing influence but also in its action in stabilizing the remanent induction. While high remanent induction must be the chief desideratum, it will be clear that it is arrived at and maintained only by means of a high coercive force. Since the demagnetizing factors for all conditions may be determined once for all, the testing and comparing of magnet steel material may be made on the basis of measuring the residual induction and calculating the remanent induction for the particular conditions of use. The coercive force values remain unchanged whether the magnetic tests are carried out either under closed or under open magnetic circuit conditions.

The practical usefulness of magnetic data has been greatly augmented by the proof that they furnish valuable information as to the mechanical and structural characteristics of those materials which are magnetic in character, as iron and steel, but are designed for use under conditions where their mechanical stability is all-important. The limitations of the microscope and the fact that hardness and chemical tests frequently fail to distinguish adequately between materials, where the magnetic test shows distinct differences, greatly augments the serviceability of this new addition to metallurgical test procedure. Comparatively great magnetic changes accompany thermal or mechanical treatment.

Waggoner<sup>2</sup> has shown that magnetic hysteresis and the maximum strength of steels vary in the same way with changing carbon content. Gumlich<sup>3</sup> has found that the coercive force of annealed steel increases linearly with the carbon content up to the eutectic and thereafter, but at a decreased rate after the eutectic is passed. Mars<sup>4</sup> has shown that there is a definite relation between the Brinell hardness and the residual induction in a series of iron carbon alloys. Burrows<sup>5</sup> has shown the wide changes in magnetic properties which accompany changes in heat-treatment procedure.

An important application of magnetic analysis in the laboratory is in the study of those materials or tools which have given exceptional performance, in order to determine wherein they differ from the routine output. The point that the test is not a destructive one warrants individual examination of more or less expensive tools, at any stage in their manufacture. Routine examination requires of course that the magnetic criteria of a standard and satisfactory tool be established initially, and the allowable limits from the manufacturing standpoint determined.

The magnetic criteria use in correlating the magnetic and mechanical properties of materials vary according to the special problems involved. Frequently a single

are found most valuable, as these values are profoundly influenced by the existent structural and hardness conditions. Experience has shown that identical specimens of raw material when subjected to the same thermal or mechanical treatment will always have the same final magnetic characteristics. Departure from standard values established once for all for a given process of handling or manufacture, after allowance is made for practical manufacturing limitations, may be made to serve as a basis for rejection or culling.

Table I gives the results of hysteresis tests upon a lot of high-speed steel twist drills furnished under a definite chemical and thermal treatment specification. The values of the material in the annealed condition is as follows:

| Specimen No.                                      | Residual Induction | Coercive Force |
|---------------------------------------------------|--------------------|----------------|
|                                                   | 17,300             | 18.2           |
| TABLE I—MAGNETIC TESTS OF HIGH SPEED TWIST DRILLS |                    |                |
| Specimen No.                                      | Residual Induction | Coercive Force |
| 1                                                 | 7100               | 41.6           |
| 2                                                 | 7000               | 48.9           |
| 3                                                 | 6980               | 44.2           |
| 4                                                 | 6800               | 47.4           |
| 5                                                 | 7030               | 47.4           |
| 6                                                 | 7130               | 47.2           |
| 7                                                 | 7040               | 48.0           |
| 8                                                 | 7100               | 50.8           |
| 9                                                 | 7150               | 42.0           |
| 10                                                | 7000               | 42.0           |
| 11                                                | 6930               | 48.0           |
| 12                                                | 6810               | 44.8           |

Considering the rather wide percentage variation shown in coercive force and bearing in mind that "the experimental evidence seems to point to the conclusion that there is one and only one set of mechanical characteristics corresponding to a given set of magnetic characteristics," it follows that certain of the above drills differ considerably from each other. The results of the magnetic test, if compared with the results of actual cutting tests, which have not been carried out on these drills, would afford information of considerable value.

Table II shows magnetic test results for a lot of carbon steel reamers, where the variation in values of coercive force from the mean is about 44 per cent.

TABLE II—MAGNETIC TESTS OF CARBON STEEL REAMERS

| Specimen No. | Coercive Force |
|--------------|----------------|
| 1            | 24.1           |
| 2            | 26.4           |
| 3            | 30.5           |
| 4            | 21.7           |
| 5            | 29.1           |
| 6            | 21.2           |
| 7            | 30.0           |
| 8            | 33.0           |
| 9            | 33.1           |
| 10           | 25.8           |
| 11           | 27.4           |
| 12           | 27.9           |

The development of apparatus for the magnetic analysis of materials has been signally backward when compared with the advances made in the general testing appliance field. This is true when the magnetic testing equipment is designed for use in what may be called purely electrical testing, where information in regard to the magnetic characteristics of materials is demanded in connection with the design of electrical machinery. It is equally true where information is desired as to the magnetic characteristics of materials or tools, in order to determine their quality or to predetermine their mechanical performance.

Until quite recently the difficulties in the way of making rapid and accurate magnetic measurements seemed insurmountable. The general problem of making

FIG. 3.—SIMPLEX PERMEAMETER

value of permeability determined under a definite magnetizing force suffices to define the state of a product, but in general one or both of the hysteresis constants

<sup>2</sup>Waggoner, "A Relation Between the Magnetic and the Elastic Properties of a Series of Unhardened Iron-Carbon Alloys," *Physical Review*, 35, pp. 58-65; 1912.

<sup>4</sup>Mars, *Stahl und Eisen*, 29, pp. 1673-1678; 1909.

<sup>5</sup>Burrows, "Correlation of the Magnetic and Mechanical Properties of Steel," *Bulletin. Bureau of Standards*, Vol. 13, p. 207. (Scientific Paper No. 272.)

such measurements centers about the determination of magnetic induction and the magnetizing force which produces this induction. The difficulties come in the determination of the magnetizing force. This force has a number of components, some of which may be calculated but others of which, due for example to the presence of joints in the magnetic circuit, may not. The presence of these joints demanded compensating adjustments for their offsetting, when the usual testing apparatus was employed, which made the test operation tedious and lengthy.

When therefore accurate magnetic test data was required the laboratory or shop had the choice of shaping their test material into a very long bar or into a closed ring, to obviate the joint difficulty, or else using a permeameter with complicated adjustments necessitating more or less skill on the part of the operator. The accurate testing of tools was usually out of the question. Most of the available permeameters which were simple in operation were notoriously inaccurate and could not be depended upon to give even comparative results save when the materials or specimens examined were practically of the same kind.

## Notes on the Use of the Pressure Gage For Pitot-Tube Measurement

BY EVALD ANDERSON

**I**N MAKING use of the Ellison or similar differential pressure gages for the measurement of small differences of pressure, as with the pitot-tube in the determination of the velocity of gases in stacks and flues, a simple modification of the ordinary connections has been found of very great advantage.

As is well known the differences of pressure that must be dealt with in gas velocity measurement are ordinarily very small. Thus, the velocity-pressure corresponding to 12 ft. per sec. at 200 deg. C. and at sea level is only about .02 inches, or two of the smallest divisions on the ordinary gage. It consequently becomes very im-

portant that the zero reading of the instrument be accurately determined, for the change in specific gravity of the liquid corresponding to the change in volume as represented by the movement of the meniscus of .01 is very slight, and the actual difference in level between any two given points on the gage is affected very little by a change of the alignment which would cause the liquid meniscus to move .01 in. On the other hand, if the actual zero reading is not known, such changes would introduce very large errors where

FIG. 2.—IMPROVED PITOT TUBE CONNECTIONS

the total pressure difference to be measured is of the magnitude of .02 in.

When using the standard gage, the usual operation is to fit the gage with two pipe nipples, one in each opening, and then to connect these to the pitot-tube by means of rubber tubing. Then to find the zero reading, either the rubber tubing is disconnected from the nipples, exposing both sides of the gage to the atmospheric pressure, or else the pitot-tube is withdrawn from the stack or flue and held in still air, thus approximating equal pressure on both the velocity and static openings of the tube. Both of these schemes are unsatisfactory. In the first case it is nearly impossible to change the rubber-tube connections without disturbing the alignment of the gage, and in the second case eddy currents are nearly always present, even in so-called still air, which affect the gage-reading.

To overcome these difficulties the connections and fittings shown in the sketch, Fig. 1, and the photograph, Fig. 2, were devised some years ago and have been used continuously since then. These consist simply of two pipe tees and nipples connected with a rubber tube, with a tube-clamp to close this connection. The pitot-tube is connected to the upper nipples by means of rubber tubing in the ordinary way as shown. When the zero point is to be read, the tube-clamp is opened, equalizing the pressure on both sides of the gage. Of course this can be done without removing the pitot-tube from the stack or flue where the gas velocity is being measured. When the liquid meniscus has come to rest, the zero reading is noted, the tube-clamp closed, and the gage is ready for the regular velocity reading. If the velocity of the gas in the flue or stack is high, it is necessary to close one of the connecting rubber tubes by doubling it up between the fingers while making the zero reading in order to insure correct results.

With these connections the zero point can be determined as often as desired and accurate results thereby insured. In place of the fittings shown it is of course possible to use regular metal or glass connections fitted with a valve, instead of the rubber tube together with Hoffman clamp.

Laboratories of the Western Precipitation Company,  
Los Angeles, Calif.

FIG. 1—SKETCH OF ELLISON GAGE AND FITTINGS

portant that the zero reading of the instrument be always known with accuracy.

This zero reading depends first on the volume of liquid in the gage, and second, on the alignment of the latter. The volume of liquid varies appreciably with the temperature of the exposed portion, while small variations in the alignment always occur from various causes. Neither of these variations introduce any appreciable error in the actual reading, provided the zero

# The Remelting of Aluminium Pig in the Electric Furnace

Electric Melting Offers Advantages in Control of Atmosphere, Temperature and Application of Heat—Description of a Plant Which Replaced Oil Furnace—Comparison of Costs

BY DWIGHT D. MILLER

Engineering Department, The Society for Electrical Development, Inc.

IN VIEW of the great success attendant upon the use of the electric furnace in the steel industry, not only for melting and refining but also for the heat-treatment of the product as well, it is only natural that there should be a demand for an electric furnace by means of which the various metallurgical processes involved in the non-ferrous field could be carried on with the same accuracy, precision and duplication of results as has characterized its use in the steel and allied ferrous fields. That there is such a demand, together with its extent and the efforts that have been and are being made to meet it, has been pointed out in a paper by the writer: "The Electric Furnace as a Medium for Heating Non-ferrous Metals," read at the annual meeting of the American Institute of Metals last September.

## ACCURACY OF CONTROL THE SALIENT FEATURE

Aside from the fact that the electric furnace has practically doubled the temperature range above zero and made it available commercially, the one great advantage secured by its use which has already established it firmly in the manufacture and conditioning of metals is summed up in the word *control*. Through no other heating medium can the same accuracy of control coupled with the nicety of adjustment and maintenance of temperature be obtained. In fact the electric furnace is pre-eminently suited for carrying out the various metallurgical processes in that by the very nature of its construction and operation it produces a non-oxidizing or reducing atmosphere.

The three vital factors involved in all metallurgical processes are atmosphere, time and temperature. Their accurate control and regulation is essential to the production of metals of the highest quality, and such control is best secured by the use of the proper type and equipment of an electric furnace.

## ELECTRICAL CONTROL

We have just seen that control of atmosphere is inherently obtained in the electric furnace. Control of temperature is of even greater importance in processing non-ferrous than ferrous metals, since the additional danger of large metal losses due to volatilization on account of superheating is always present in the case of the former. Greater accuracy of temperature control and its regulation is secured when the electric furnace is used because of the peculiar nature of electric heat and the method of its application.

Electric energy is changed into heat at 100 per cent efficiency regardless of temperature and so applied that it is concentrated at definite points or confined within a definite area in the furnace; furthermore it can be generated in any quantity regardless of temperature,

which feature is unique and renders its utilization more flexible, more efficient and the more readily controlled. On the other hand it is the lack of control of the various factors involved in the production of the heat itself as well as the nature of the appliances that renders the heat of combustion less flexible, less efficient and hinders its control.

In the one case electric energy is conducted, with but a slight loss, by means of overhead cables, which are pliable and readily portable to the exact location in which the heat is to be generated and there changed into heat without any loss by merely throwing a switch. With any given furnace, the electrical conditions, such as the line voltage, resistance of leads, electrodes, and resistor material are fixed so that the same amount of current must flow, producing the same temperature to an exact degree time and time again, and the only heat losses that must be taken care of are those due to radiation and conduction.

Moreover when it is necessary to change the temperature according to the requirements of the process it can be accurately varied in finely graded steps by voltage control—since in this case wattage is temperature.

## COMBUSTION CONTROL

In the other case, liquid or gaseous fuel must be conveyed under pressure with an appreciable expenditure of

FIG. 1.—TAPPING TYPE OF STATIONARY FURNACE

energy in rigid, stationary pipe lines which are not portable and take up valuable space. If solid fuel is used, such as coal or coke, the case is all the more exaggerated. Upon arriving at the point of ignition the fuel must be mixed with the oxygen of the air before combustion takes place, but in order to get perfect combustion, so that there shall be 100 per cent efficiency, it must be

mixed with a definite minimum quantity of the oxygen of the air, a condition most difficult to control and rarely if ever encountered in commercial practice.

In fact statistics show that the average thermal efficiency of high temperature combustion furnaces as used in non-ferrous work is in the neighborhood of 7 per cent. The control of the degree of temperature as well as its gradations are much more difficult and complicated on

FIG. 2.—SECTIONAL ELEVATION OF FURNACE

account of the many variables involved as well as the errors of the human element always present with manual control. In addition to the heat losses due to radiation and conduction, there is the additional and greatest source of loss, i.e., heat lost by convection.

With natural draft, the draft is seldom known and not only changes from day to day but also often during each day in accordance with the variation in the direction and velocity of the wind and the humidity of the air. This condition is beyond human correction.

These advantages which are inherent in the case of electric heat more than offset its higher first cost in many instances. Many items enter into the entire cost of the finished product of which cost of heat is only one. If therefore by its use other items, such as time, labor and fire insurance, are cut in greater proportion producing a metal of higher quality—hence one commanding an increased selling price—it is evident that not only is electrically generated heat cheaper to use, but also its use is imperative in order to compete successfully with those using it in similar processes.

#### ALUMINIUM DROSS

Aluminium is not what is known as a volatile metal, it is however a very sensitive metal, absorbs impurities readily and has an affinity for oxygen, especially at high temperatures. This property has led to its use as a de-oxidizing agent, since in combining with oxygen an aluminium oxide ( $Al_2O_3$ ) known as dross is formed and can be skimmed off with the slag.

When melting aluminium pig—high-grade aluminium—if heated metal is allowed to come in contact with an oxidizing atmosphere, the loss due to dross may be as great as 5 per cent, since some of the elemental metal becomes entangled with the aluminium oxide during the

process of skimming and is lost. Hence it is most important that the melting be done in a neutral or de-oxidizing atmosphere.

#### USES OF ALUMINIUM

With the large increase in the production of aluminium by the electric process has come naturally a greater demand not only for the pure metal but also for the aluminium alloys. One of its most important uses at present is found in the manufacture of parts for the timing devices used in connection with shrapnel. Aluminium for this purpose is usually sand cast under very high pressure, thus providing a denser metal as well as a metal with increased strength. Other important uses are found in the aeroplane and automobile industries, which use large quantities of both the pure metal and the alloys, the latter combining the lightness of aluminium with the strength of the alloying material such as steel. This property is especially valuable in the manufacture of aeroplanes in which human life is dependent upon the ability of the material to withstand successfully severe and repeated sudden stresses and strains. Still other uses for the metal are found in the manufacture of aluminium foil, bottle caps, tubing for store service, rolled rods and reinforced aluminium conductors.

#### PROCESS AT THE U. S. ALUMINUM COMPANY

About one-half of the total amount of aluminium used in this country is manufactured in the plant of the United States Aluminum Co., at Massena, New York. Here the pig metal as it comes from the reduction plant

FIG. 3.—SIDE ELEVATION OF FURNACE

is remelted for the purpose of casting it into ingots or rolling billets. A number of aluminium alloys are also made and the metal heat treated in the electric furnace after having been rolled or drawn into rods or conductors. The object of this remelting is to cleanse the metal by removing in this manner the slag and scum contained from the reduction process. After the remelting there is a distinct and marked difference in its appearance, as it loses its dull finish and is much brighter.

Since a very great quantity of aluminium is handled at this plant, even the smallest saving in metal loss is important and soon manifests itself in the aggregate

savings. Hence, with the idea of experimenting with just what could be done in the way of affecting savings as well as in improving the quality of the metal, the United States Aluminum Co. installed electric furnaces both for remelting and heat treating the metal.

### THE FURNACE

The furnace selected for remelting is a stationary resistance type and has a bowl shaped hearth capable of holding three to four tons of molten metal which is discharged by tapping. It is rated at 500 kw. and designed for single-phase, 25-cycle operation.

The enclosure is rectangular and made of sheet metal suitably insulated with high-grade fire clay bricks and backed up with heat insulating material in the space between them and the metal shell. There are doors at either end of the furnace together with three rabbling doors on the side opposite the tap hole. These doors are heat insulated in the same manner as the body of the furnace. Those at the ends are opened and closed by sliding up and down vertically, being actuated by compressed air. The rabbling doors swing open on hinges. Running lengthwise with the furnace along either side are resistor troughs also rectangular in section but open at the top, made of highly refractory carbide mixed with a binder so that they can be easily molded. They are filled with resistor material consisting of finely broken carbon or graphite and supported on separate brick piers which serve to dissipate the heat generated in the troughs and diffuse it uniformly, thus avoiding hot spots in the refractory lining in the immediate vicinity of the troughs. Current enters the troughs through large copper terminals attached at the ends, making contact with the resistor material which becomes incandescent throughout in the same manner as the filament of an incandescent lamp. The heat thus generated is radiated mainly to the furnace roof and from there reflected down on the hearth and the material being treated.

Such construction provides a simple, durable and strictly commercial furnace, since all material used can be readily obtained in the open market; one in which both the atmosphere and temperature is under positive and accurate control.

When running continuously the furnace can melt one ton per hour which is tapped into graphite crucibles holding about 125 pounds. The daily output of the furnace is twenty tons.

### ELECTRICAL EQUIPMENT

Single-phase 25-cycle current enters the building at 2200 volts and is there stepped down to 500 volts, at which pressure it enters the primary side of a special regulating transformer always provided with the furnace. This transformer consists of 9 selective, oil-break, hand-operated switches by means of which the temperature is regulated and held constant by voltage control. The actual voltage required varies with the resistance of the resistor material in the troughs and the required degree of temperature of the material being processed. That actually used in the furnace ranges from 500 down to 240 volts.

In addition to the usual operating main line switch, there is an indicating and integrating wattmeter, also

a pyrometer mounted on the switchboard. This pyrometer is connected to a thermocouple which protrudes through the roof well into the furnace. Hence an accurate record is had at all times of the amount of power being consumed, the total consumed each day as well as the degree of temperature attained.

### OPERATION

Upon closing the main line switch, current at full operating pressure flows through the resistor material. Due to the negative temperature coefficient of this material (broken carbon or graphite), it is a poor con-

FIG. 4.—POWER CONSUMPTION CURVE

ductor when cold and offers resistance to the passage of the current at the start. This resistance transforms the electrical energy into heat, and the resistor material begins to heat up. The hotter it gets the better electrical conductor it becomes, and more current flows, soon raising the material to an incandescent heat. Any tendency to overpower the furnace is immediately indicated by the wattmeter on the board and quickly corrected by connecting one of the selective oil-break switches which lowers the voltage and checks the power input. There is a slight voltage fluctuation during this heating-up period, but as soon as the troughs have attained the desired temperature the resistance of the resistor material remains practically constant and the current flow automatically adjusts itself to a steady inrush. The special regulating transformer is also used to secure accurate adjustments in the degree of temperature in accordance with the requirements of the material under treatment.

### CHARACTERISTICS OF THE FURNACE

Curves are here given showing the power input necessary to bring the furnace up to operating temperature, also the rate of cooling. These curves apply to a 50 kw. annealing furnace in use at the plant, but of the same electrical design and construction as the melting furnace. It will readily be seen from the cooling curve that having once attained temperature, the furnace retains the heat to a remarkable degree—in other words is sluggish. This characteristic is used to great advantage in keeping down the amount of power required to carry on the process, especially under continuous operating conditions as is here the case. For instance, with the furnace full of molten metal, the pyrometer indicating a

temperature of 1050 deg. C. (1922 deg. F.), which means that the bath was about 850 deg. C. (1562 deg. F.), on account of the temperature head between roof and bath, this temperature was maintained constant with the regulating transformer on only the fourth step and an input of 265 kw., and this under the condition of continuous addition of cold metal as the hot metal was tapped from time to time. In another plant where the

FIG. 5.—RATE OF COOLING

furnace is operated intermittently they make the last heat of the day on practically the stored energy of the furnace.

After the metal is tapped it is cast into ingots or rolling billets and either sold to the trade or further worked in the plant.

The castings are subjected to a pressure of 25,000 pounds per square inch by means of molds operated by a horizontal hydraulic ram. This ram is situated in the center of the press with the molds on either end of the shaft. As the pressure is exerted on one set of molds the others are opened and the castings removed.

Several kinds of alloys, some containing zinc, are also made in the plant, and it is in this process that the greatest savings are made by the use of the electric furnace. Metal losses due to an oxidizing atmosphere as well as those due to volatilization and the carrying off of fine particles by convection currents, which in some cases is the greatest source of loss, are entirely eliminated. In fact, it is the possibility of the elimination of just such losses as these that is rapidly establishing the electric furnace in the same position in the non-ferrous field as it now occupies in the ferrous industries.

#### ANNEALING

In order to relieve the metal of the stresses and strains produced in working it, also to further develop the inherent physical characteristics of the alloys, some of the product is annealed in an electric furnace of the same general type as that used for melting.

It is now a well recognized and established fact that heat treatment contributes more to the superior physical qualities contained in various alloys than does the addition of the alloying elements.

The annealing furnace is known as the car type and while originally rated at 50 kw. it is often worked with a power input of 100 kw. The platform of the car is made of fire-clay brick, on which the material to be treated is loaded in such a manner as to allow of free circulation of the radiated heat around all parts of the charge and its even penetration.

The loaded car is run in and out of the furnace, which has only one door, on tracks, being actuated by motor-driven gearing located beneath the floor.

The capacity per hour of metal treated as well as the time it is left in the furnace together with the degree of temperature used will depend upon the material being processed. The temperature generally used however varies from 350 to 500 deg. C. (662 to 932 deg. F.) and the time from two to five hours.

The furnace is also equipped with a special regulating transformer, switches, wattmeter and pyrometer so that the same degree of accuracy of control and recording of conditions at all times is had as is the case with the remelting furnace.

A curve is here given showing the time required to anneal different amounts of aluminium with a steady input of 50 kw. per hour starting with a hot furnace 425 deg. C. (797 deg. F.) which is held constant.

#### RESULTS OBTAINED

The advantages which are secured by the use of the electric furnace are summed up by Mr. H. M. Hall, Superintendent, as follows:

- 1.—The electric furnace replaced an oil furnace burning crude petroleum oil which produced large losses, particularly in the case of alloys containing volatile constituents such as zinc.
- 2.—The electric furnace gives much more uniform mixtures with much less losses.
- 3.—The cost of electric power compares very favorably with the increased cost of fuel oil which was becoming prohibitive.
- 4.—Savings are effected by the use of the electric furnace in that the metal losses are less and the thermal efficiency greatly increased.
- 5.—Where coal fired furnaces are used, there is a saving of one or two men in favor of the electric furnace.

FIG. 6.—ANNEALING TIME

6.—There is also a saving in space required per pound or ton of metal melted in favor of the electric over the coal fired furnace.

7.—The electric furnace is a much cleaner, cooler furnace for the men to work around than is the case with an externally fired fuel furnace.

It is evident that while improved quality of product was the end sought, economy of operation resulted from the use of electricity as the heating medium.

# Synthetic Phenol\*

Description of Old Process Used Prior to Introduction of Dennis-Bull Process—Great Economies Effected in Use of Sulphuric Acid and Caustic Soda as Well as in Transportation of Raw Materials

By A. G. PETERKIN

IT IS difficult to estimate the quantity of any of the products from coal tar which are available, because on the one hand the production of tar is changing from day to day, due to the continued increase in the number of coke ovens, and on the other hand its consumption for fuel purposes is affected by greater or less difficulty in obtaining supplies of coal. It is safe to say, however, that it would not be practical or even possible to-day to make more than five to six million pounds of phenol per year from this source.

The United States used before the war some 5,000,000 lb. of phenol per year, the consumption being divided between pharmaceuticals, resins of the Bakelite type, dyestuff intermediates, and the explosive, picric acid. At the beginning of the war the demand immediately increased, due to the increased manufacture of picric acid. The French Government particularly became a large customer of manufacturing concerns in this country, both for phenol and picric acid. The production just before the entrance of this country into the war had jumped to something like 72,000,000 lb. of phenol per year.

It is likely that 1919 will see a very great increase in the production of phenol in this country. Coal tar as a direct source of phenol is therefore a negligible factor in view of the present demand.

Whatever the merits of picric acid as an explosive, a real objection to its manufacture in such times as these lies in the relatively enormous amount of raw materials involved, and the necessity for the correspondingly great consumption of our valuable transportation facilities. For example, to make 100,000,000 lb. of synthetic phenol requires in round numbers:

|                                   | Pounds      |
|-----------------------------------|-------------|
| Benzol .....                      | 115,000,000 |
| Fuming Sulphuric Acid (9½%) ..... | 280,000,000 |
| Caustic Soda .....                | 180,000,000 |
| Lime .....                        | 42,000,000  |
| Limestone .....                   | 190,000,000 |
| Coke .....                        | 35,000,000  |
| Niter Cake .....                  | 42,000,000  |
| Total .....                       | 884,000,000 |

or nearly nine times that of the finished product, using the generally adopted process and working with fair economy. To say that it is an extravagant process is to put it mildly, but it has maintained itself with considerable obstinacy in the face of many attempts to improve and shorten it.

## OUTLINE OF OLD PROCESS

The illustration, Chart I, shows the old process diagrammatically. It has been described many times, and a bare outline will suffice now. Benzol is sulphonated at temperatures varying from 50 to 70 deg. C. The

strongest acid that may be used with economical results in the writer's opinion is fuming sulphuric acid containing 9½ per cent of free SO<sub>3</sub>, the limitation being enforced by the necessity of avoiding the formation of diphenyl-sulphone. Since the composition of the spent acid from the sulphonation is a constant, the amount of sulphonic acid necessary for the completion of the reaction is increased very largely as the concentration of the initial acid is decreased. It has, therefore, not been considered economical to use acid weaker than one containing 98 per cent H<sub>2</sub>SO<sub>4</sub>. The figures given above are for the higher concentration. The result of the sulphonation is a solution of sulphonic acid, sulphuric acid and water. The sulphuric acid and water together make a spent acid of approximately 80 per cent H<sub>2</sub>SO<sub>4</sub> and 20 per cent H<sub>2</sub>O. The solution then contains in round numbers 60 per cent sulphonic acid and 40 per cent spent sulphuric acid. The sulphonic acid is required in the form of sodium salt.

The procedure in all plants is essentially the same, although many minor variations have been adopted. Slaked lime is placed in the agitators and the mixture of sulphonic and sulphuric acid slowly added during agitation. The sodium salt may be formed by addition of sodium sulphite obtained from the fusions later in the

CHART I.—OLD SYNTHETIC PHENOL PROCESS

process. When this procedure is adopted, the mixture in the agitators consists of a water solution of sodium benzene sulphonate and a mixture of solid calcium sulphite and calcium sulphate. The whole is heated to 115 deg. C. in order to obtain the sulphate in proper crystalline form for filtering, and is passed through the filter presses. The resulting solution of sodium benzene sulphonate contains approximately 12 per cent of the salt and small quantities of calcium sulphate, due to the slight solubility of this material.

It is important to remove all calcium salts, both for the sake of the tubes in the evaporators and because of the havoc they cause in the fusion operation. This is accomplished by the addition of the necessary small amount of sodium carbonates and refiltration. Some

\*A paper read at the meeting of the Amer. Inst. of Chem. Eng., Gorham, N. H., June 19-22, 1918.

FIG. 1.—SULPHONATORS, TOP VIEW  
FIG. 3.—DRUM DRYERS

FIG. 2.—FILTER PRESSES  
FIG. 4.—GENERAL ARRANGEMENT SPENT ACID PLANT

factories make the soda salt in two steps, adding sodium carbonate to the filtered solution of calcium benzene sulphonate; others add only the amount of lime necessary to react with the sulphuric acid, in making the soda salt in one step, which makes the use of the by-product sulphite difficult, due to the liberation of  $\text{SO}_2$ . The 10 per cent solution is evaporated down to the saturation point, and the salt obtained from the syrup by means of drum dryers. The salt, preferably retaining about 10 per cent of water, is fed into melted caustic soda in the fusion kettles, there being about one molecule of soda in excess. The temperature during the fusion is maintained between 320 and 350 deg., the salt being fed in slowly during the operation.

The critical temperature of the reaction appears to be 320 deg. C. As the result of the fusion, a light brown liquid mass with the appearance of melted chocolate is obtained, which is poured hot into such an amount of water as will dissolve the phenolate and leave the sodium sulphite in solid form. This is done in vessels marked "dissolvers" which are provided with stirrers. Only about 10 per cent of the sulphite formed remains in the solution and this amount can undoubtedly be decreased. The phenolate liquor is filtered from the sulphite on open sand filters. The sulphite is agitated with water, separated by means of filter presses, washed

free of phenol and marketed as an impure sodium sulphite. A typical analysis of this material is:

|                                          | Per Cent |
|------------------------------------------|----------|
| Moisture .....                           | 24.20    |
| $\text{Na}_2\text{SO}_3$ .....           | 7.12     |
| $\text{Na}_2\text{SO}_4$ .....           | 62.30    |
| Insol. in hot $\text{H}_2\text{O}$ ..... | 0.46     |
| $\text{CaH}_2\text{ONa}$ .....           | 0.60     |

The wash water is used in the dissolvers so that its sulphite is deposited again on the filter beds.

The phenolate liquor is carefully diluted to a gravity corresponding to a phenol content of about 16 per cent. This diluted solution is placed in a series of tanks, and 30 per cent carbon dioxide gas generated from a mixture of coke and limestone passed through it. These so-called "blowers" are arranged so that the gas may pass from one to another in any direction desired. The strong gas goes first through the almost neutralized phenolate and leaves from a strongly alkaline solution, thus avoiding any possibility of loss due to the vapor pressure of phenol at the temperature of the spent gases involved which is about 50 deg.

It is impossible to entirely neutralize the phenolate solution by means of carbon dioxide in one operation, at any rate, unless such a large excess of  $\text{CO}_2$  is introduced as to transform all the carbonate to bicarbonate, which is undesirable. When the passage of the gas is

FIG. 5.—SULPHONATORS, SIDE VIEW  
FIG. 7.—EVAPORATORS AND DISSOLVERS

FIG. 6.—AGITATORS  
FIG. 8.—COOLERS

discontinued the phenol layer contains in solution about 10 per cent phenol as sodium phenolate, while the carbonate layer is free from phenolate but contains approximately 2 per cent of phenol. The carbonate is completely freed from phenol by means of a steam dis-

tillation; a 4 per cent solution of phenol is obtained in this way. The crude phenol containing 10 per cent of phenolate may be completely acidified with  $\text{CO}_2$  by replacing the carbonate solution with water. Niter cake, however, used as an acidifying agent has the ad-

FIG. 9.—RECORDING GAGE, AUTOMATIC TEMPERATURE CONTROL  
FIG. 11.—FINAL WASH TANK AND RECEIVER

FIG. 10.—WASHERS  
FIG. 12.—TWO SMALL PUMPS ONLY REQUIRED IN THE PROCESS

vantage of simultaneously removing a large percentage of the water present. The dehydration reduces the water content of the crude phenol from 30 to less than 14 per cent and relieves the refining stills of a great burden. The crude acid is placed in a simple still from which is obtained a first fraction of water and phenol, a middle fraction of pure phenol and a residue of the more complex phenolic bodies formed in the fusion. The synthetic phenol produced is exceedingly pure; it is comparatively easy to obtain material melting at 40 deg. C. Redistillation gives a product melting at 40.6 deg. The true melting point of pure phenol is in our opinion 40.8 deg.

#### ECONOMIES TO BE EFFECTED IN THE PROCESS

The great economies possible in the process are obviously to be made in the cutting down of the 100 per cent excess of sulphuric acid, the reclaiming of the caustic soda and the marketing of the sodium sulphite in a useful and valuable form. The maximum yield which has been claimed for the process is about 80 per cent. Our work has shown that the fusion operation alone will not give more than 90 to 92 per cent of the theoretical yield; in practice it is difficult to maintain this high standard. Under present conditions, the average American practice probably results in a total

overall yield of between 60 to 75 per cent. As chemical processes go, the process requires an inordinate amount of labor and the repeated handling of the material gives ample opportunities for mechanical losses, particularly in view of the present restlessness of workmen.

Two methods have been suggested to reduce or conserve the excess of sulphuric acid used. Daniel Tyrer of England (U. S. Patent, No. 1,210,725) passes benzol vapor through sulphuric acid of as low concentration as 90 per cent  $H_2SO_4$  at temperatures varying between 100 and 185 deg. C. That part of the benzol vapor not reacted upon carries with it to a condenser the water of reaction, and so gives a constant concentration to the sulphuric acid, keeping it active. Tyrer claims in this way to get about 80 per cent of the amount of sulphuric acid theoretically obtainable from the sulphuric used. This method has not yet been tried on a large scale in this country.

#### METHOD OF DENNIS AND BULL

The second method is that of Dennis and Bull, the practical application of which has been worked out by the Barrett Company. Some two years ago, Professor L. M. Dennis<sup>1</sup> at Cornell University discovered that al-

<sup>1</sup>U. S. Patents, Nos. 1,212,612, 1,211,923, 1,227,894, 1,228,411 and 1,229,593.

though the solubility of pure sulphonic acid in benzol was negligible, benzol would take up from the mixture of sulphuric and sulphonic acids between 2 and 3 per cent of its own volume of the sulphonic acid. In working out this idea it occurred to Mr. Hans Bull of that company that the sulphonation could be made simultaneously with the extraction. These ideas have been utilized in the evolution of an extremely simple process which not only saves 90 per cent of the excess sulphuric acid as a spent acid containing 70 to 77 per cent  $\text{H}_2\text{SO}_4$ , but eliminates a good percentage of labor, all the lime, and substantially reduces the deplorable cost of repairs, due to the many moving parts of the old installation.

The process will be easily understood from Chart II. The vessels 1, 2, 3 and 4, so-called "extractors," contain at rest a layer of a solution of sulphonic and sulphuric acids of varying proportions. The benzol passes continually upward through this series of extractors, the vessels being under a pressure equivalent to the head of benzol. The distribution of the liquid in fine bubbles is effected by means of perforated branch pipes. After the passage of the benzol for a certain length of time, the solution in No. 1 is free from sulphonic acid and consists of 77 per cent  $\text{H}_2\text{SO}_4$ . When this has been accomplished, the so-called "spent acid" is withdrawn. The solution in No. 2, which probably contains 10 per cent of sulphonic acid is dropped into No. 1. The solution in No. 3, which contains probably 25 per cent sulphonic acid is dropped into No. 2, and the solution in No. 4, which contains probably 40 per cent sulphonic acid is dropped into No. 3.

Into No. 4 is then slowly introduced a charge of 98 per cent sulphuric acid. The flow of benzol is not interrupted at any time. Sulphonation takes place almost immediately and the volume of the benzol flowing through, approximately 200 gallons per minute, is so great as to effect almost instantaneous removal of the heat of reaction. The benzol is maintained throughout at a temperature of 60 deg. C. by heaters at the bottom of the system and coolers at the top.

After passing through the coolers, the benzol, which will contain approximately 2 per cent sulphonic acid, passes successively through the washers, 5, 6 and 7, containing water. The benzol falls from one vessel to another by gravity, there being no pressure on this part of the system. The sulphonic acid remains in the water and the benzol leaves the last washer entirely relieved of its burden. It is passed to large settling tanks where the rate of flow is slowed down to such an extent as to allow the sulphonic acid solution, carried in suspension, to settle, and from these tanks flows to the pump and is forced through the heaters to the extracting system once more.

When such an amount of sulphonic acid has been deposited in Washer No. 5 as to bring it to the strength desired, it is removed to an evaporator and the solution from Washer No. 6 pumped to No. 5, and that from No. 7 to No. 6. Fresh water is put into No. 7. A water solution of sulphonic acid can be obtained containing 60 per cent or even more sulphuric acid and containing also about 2 volumes per cent of benzol in solution. The benzol is removed by evaporating a small percentage of the water. The solution of sulphonic acid is then neutralized, either by the carbonate solution

from the phenol blowers or with the solid sulphite of soda. The sodium benzene sulphonate obtained contains some 5 or 6 per cent of sodium sulphate, due to

CHART II.—FLOW SHEET, DENNIS BULL PROCESS

the solubility of sulphuric acid in the benzol solution of sulphonic acid (one part sulphuric to twenty parts sulphonic).

#### ADVANTAGES OF THE PROCESS

The advantages of the process are obvious. The initial cost of the plant is about 50 per cent of that of the old style plant, which it displaces. Moreover, it runs practically without attention and requires from one-third to one-fourth the number of laborers. Tak-

<sup>1</sup>U. S. Patents, Nos. 1,247,499 and 1,260,852.

ing for granted complete extraction of the sulphonic acid, which proves quite possible, and a removal of the benzol from the water solution of sulphonic acid, the losses possible are confined to mechanical causes, that is, either leaks or evaporation. The yield under the old process, from benzol to sodium benzene sulphonate, is about 90 per cent. The new process makes easily possible a yield of 98 per cent, leaving the mechanical losses out of consideration. The formation of disulphonic acid and of sulphone is negligible. The operations: (1) discontinuous sulphonation, (2) liming, (3) filtering, and (4) evaporating, involving complex machinery and many moving parts, have all been displaced with the one simple and continuous operation, extraction and sulphonation going on simultaneously, the only moving parts being two small pumps. The enormous simplification of the process achieved will be made more evident by photographs shown in Figs. 1 to 12 than by any description. The spent acid is concentrated to 93 per cent and used repeatedly.

Another improvement in the process very generally adopted has been the so-called "liquid fusion," by means of which the drum dryer with its dust and spatter has been eliminated. Liquid fusion consists in the introduction of a saturated solution of sodium benzene sulphonate directly into liquid caustic soda at a point above the reaction temperature. The reaction, when the temperature is properly controlled, goes even more smoothly than with the solid, since there is no tendency to dust and float, and the rapid evolution of the steam gives better agitation. The fusion is a great source of loss in yield. Well conducted fusions, where the temperature has been kept down and which for that reason show no evidence of oxidation, give between 86 and 90 per cent yield. Our experience shows that using the liquid fusion method, a high yield is more easily obtained than with the dry salt.

#### ECONOMY OF CAUSTIC SODA

So much for innovation. Another important economy to be achieved in this process, and one even more important than that of sulphuric acid, is that of caustic soda. Neutralizing the phenolate with sulphuric acid, as is often done, is a gross and inexcusable waste. Providing that the lime can be utilized, the difference in cost between the neutralization with  $\text{CO}_2$ , as generated from limestone, and with sulphuric acid is immeasurably in favor of the former and the operation is exceedingly simple, once the necessity for clear solutions is understood and the fact of the solubility of phenolate in phenol recognized. If any salts are precipitated by the carbonation of the phenolate, an emulsion is obtained from which the phenol will settle only with great difficulty. The avoidance of this emulsifying is merely a question of dilution, however, and no real obstacle is involved. The soda, not only of the phenolate, but the excess soda, is gotten in the form of a weak solution of sodium carbonate, which can be readily causticized and made available for the fusion operation.

The fusion reaction is:

If half of the sulphite is used for the formation of the soda salt, only one molecule of soda is consumed and this goes out of the plant in the form of sodium sulphite, a useful and marketable product. Since in the

Barrett process  $\text{SO}_2$  is evolved from the neutralization of the sulphonic acid, it is possible also to produce bisulphite of soda.

The large amount of limestone needed is not a relatively important objection from the point of view of cost, but it presents a transportation problem of considerable magnitude. The disposition of the calcium carbonate sludge from the causticization may, and in our case does, involve considerable expense. From the point of view of transportation alone, the calcination of the carbonate sludges, in rotary kilns, as a source of  $\text{CO}_2$  and of lime is justified. This has been successfully tried in connection with other operations and has been found economical in districts somewhat remote from the limestone fields.

The various economies indicated will result in a startling decrease of raw materials:

|                      | Per Cent |
|----------------------|----------|
| Sulphuric acid ..... | 40,      |
| Caustic soda .....   | 60,      |
| Lime .....           | 90,      |
| Limestone .....      | 100,     |

and a corresponding decrease of tonnage to be transported from a total of 884,000,000 to 397,214,400, per million pounds of phenol, or about 50 per cent.

#### Paint Thinning Calculations

In producing a standard weight per gallon of paint or varnish mixture, the cross subtraction scheme is valuable, because of being easily remembered as well as giving accurate ratios readily. For example, if an eight pound to the gallon paint is desired, the materials to be mixed being 20-lb.-gal. paste and 7.5-lb.-gal. linseed oil, then:

$$\begin{array}{l} \text{(Paste)} \quad 20 \times 8 \leq \frac{1}{2} \text{ gal.} \\ \text{(Oil)} \quad 7\frac{1}{2} \leq 12 \text{ gal.} \end{array}$$

The gallon weights, 20 for paste,  $7\frac{1}{2}$  for oil and 8 for the desired mixture are set down as in the above and the differences taken as the equations indicate, no attention being paid to positive or negative signs. The differences  $\frac{1}{2}$  and 12 are the ratio numbers. Thus, to every half gallon of paste, twelve gallons of oil must be added, in order to obtain an 8-lb.-gal. paint. Now if a ton of 8-lb.-gal. paint is desired, 250 gallons must be made, the ratio  $\frac{1}{2}$  to 12 or 1 to 24 requiring for this mixture 10 gallons of 20-lb. paste and 240 gallons of  $7\frac{1}{2}$ -lb. linseed oil. If it is desired to thin this paint to 7 lb. 15 oz. with spirits of turpentine (7.2-lb.-gal.) or naphtha (6-lb.-gal.) each calculation is as follows:

$$\begin{array}{l} \text{(Paint)} \quad 8 \times 7.94 \leq 0.74 \text{ gal.} \\ \text{(Turpentine)} \quad 7.2 \leq 0.06 \text{ gal.} \\ \text{(Paint)} \quad 8 \times 7.94 \leq 1.94 \text{ gal.} \\ \text{(Naphtha)} \quad 6 \leq 0.06 \text{ gal.} \end{array}$$

So that the gallon ratio of paint to thinner would be 74:6 and 194:6 respectively. As two hundred and fifty gallons of 8-lb.-gal. paint are to be thinned; the gallons of thinner to be added would be:

$$\text{Turpentine, } \frac{250}{74} \times 6 = 20.27 \text{ gal.}$$

$$\text{Naphtha, } \frac{250}{192} \times 6 = 7.8 \text{ gal.}$$

As the pigment concentration is a function of the gallon weight, it is considered good practice to regulate paint mixture by gravity as well as by viscosity tests.

## Synopsis of Recent Chemical and Metallurgical Literature

**Tin-Wolfram Concentrators.**—*Chemical Engineering and Mining Review* for December, 1917, contains an article by JOSEPH MILLER on the concentrator at Storey's Creek, Tasmania, and the issue for June 5, 1918, contains similar information on Butler's Tin Mine, Torrington, N. S. W.

The Storey's Creek ore contains massive, easily detached, wolframite and cassiterite, amenable to hand picking. Their mill, of a capacity of 30 tons per eight hours, is shown in the diagram (Fig. 1) which requires no elaboration, except as to the table section. The concentrates from the three coarse tables are treated in a hydraulic cleaner, which eliminates the fine pyrite, and the overflow is retreated on the slime table. The middlings are re-treated, being fed by water jet when poor ore is being sent to the mill. Overall recoveries are said to be above 85 per cent. The concentrates are treated in two Thompson-Davies electro-magnetic separators. Classification, like drying, is absolutely necessary as a preliminary to this step. The screen classifier

FIG. 1.

consists of a series of sieves, the coarsest having six holes per inch; while oversize is returned to the rolls. Each magnetic machine has three poles and three discs and a 15-in. feed belt. The feed is delivered by means of glass funnels, discharging on an inclined smooth convex plate which spreads the material in a thin even layer on the belt, of a thickness about equal to the size of the particles being fed.

At Butler's Tin Mine, as shown in the flow sheet in Fig. 2, three methods of concentration are in use. Wet

concentration practiced in the primary plant recovers 80 per cent of the tin contained in the ore, and about 67 per cent of the tungsten and lead. The concentrate analyzes to Sn 53, WO<sub>3</sub> 12, and Pb 5 per cent, which is too high in lead for disposal. The latter is almost

FIG. 2.

completely recovered in a M. S. flotation unit, and the tin and tungsten separated magnetically after drying. The overall recovery is considered good in view of the excessive amount of slimes produced.

**Influences of Positive and Negative Ions on Concrete**—Mr. J. C. Witt in the *Philippine Journal of Science*, 1918, 15A., p. 28-29, gives an account of the influence of several salts on the setting of cement. Comparative conditions were not arranged so that general deductions can not be drawn. Experiments were made with four cements and eleven salts under similar conditions—chlorides (Na, Zn, Cu), nitrates (Na, K, NH<sub>4</sub>), sulphates (Na, Zn, Cu) and bicarbonates (Na, K). The effect was generally to lower the tensile strength, and any increase, which was usually associated with sulphate, was very small. The cement with the highest content of calcium seemed to be affected the most. The sulphates and chlorides of zinc and copper caused a retardation in the initial set, which increased with the concentration. The other salts caused a varying retardation which reached a maximum and then diminished. The positive ion seems to have the greater influence, which would naturally be expected, inasmuch as it would effect the ionized calcium.

## Recent Chemical and Metallurgical Patents

**Leaching Process.**—EVALD ANDERSON, of Los Angeles, patents a process of leaching copper ores containing carbonates by means of an electrolyte containing ferrous salts, which effectually prevent the precipitation of insoluble copper compounds. As a specific instance he agitates one ton of 0.5 per cent copper ore containing some limestone with two tons of leach containing 1 per cent Cu as  $\text{CuCl}$ , 0.5 per cent Fe as  $\text{FeCl}$ , 5 per cent NaCl, and 5 per cent  $\text{CaCl}_2$ . The  $\text{CuCl}$  takes the copper into solution as  $\text{CuCl}$ . Ordinarily, insoluble copper compounds would be formed as follows:

In the presence of ferrous chloride, however, these insolubles are partly dissolved and partly reduced, thus:

$$3\text{CuCO}_3 + 3\text{Cu(OH)}_2 + 4\text{FeCl}_2 + 3\text{H}_2\text{O} = 4\text{Fe(OH)}_3 + 2\text{CuCl}_2 + 4\text{CuCl} + 3\text{CO}_2$$

In the last reaction, ferrous iron is oxidized by cupric copper, the reverse of the usual reaction:

In this case, however, the concentration of ferric ions is reduced to such an extent, due to the insolubility of the hydrate, that the usual reaction is reversed.

After agitation the leach solution is withdrawn and the ore washed, the combined leach and wash water

passing through an electrolytic chlorine cell, when the ferrous chloride is oxidized to ferric chloride, and the latter oxidizes cuprous chloride to cupric chloride. Sufficient NaCl is added to bring the sum of NaCl and  $\text{CaCl}_2$  up to 10 per cent, when the original leach is reconstituted. The total iron in the solution is kept balanced by selection or concentration of the ore, or by oxidizing and precipitating an excess with carbonates present in the ore. A deficiency would be made up by adding suitable salts. Precipitation of dissolved copper may be effected in the electrolytic tank, when the deficit of iron would be made up as above. (1,263,727; assigned to International Precipitation Co., Apr. 23, 1918.)

**Cerium Fluorides.**—In the method of preparing non-hygroscopic cerium and other rare earth fluorides from the sulphuric acid extraction of monazite sands in connection with the manufacture of thorium compounds for Welsbach mantles, MR. DEAN BURNS of Lakewood, Ohio (assignee, National Carbon Co., Cleveland, Ohio), has patented the process of washing the occluded sulphates from the fluoride precipitate with a solution of sodium fluoride in accordance with the following equation:

where M represents the occluded rare earth metal. This reaction takes place slowly at ordinary temperatures, but upon calcination runs to completion. This treatment produces an almost 100 per cent pure precipitate, whereas without the washing 20 per cent of occluded sulphates would be present, making the product very hygroscopic and unfit for use in the manufacture of arc lamp electrodes. (1,272,375, July 16, 1918.)

**Pyridine from Ammonium Sulphate Mother Liquor.**—Messrs. FRANK E. DODGE of New York and FREDERICK H. RHODES of Philadelphia patent the process of recovering the pyridine bases from the bath liquor of the direct or semi-direct ammonium sulphate process by the neutralization of the bath liquor with ammonia, etc., and consequent decomposition of the pyridine sulphates, and the subsequent recovery of the freed water-insoluble pyridine bases from such neutralized baths by agitating the solution with a pyridine oil solvent, which is readily separated and the pure pyridine bases distilled therefrom. The purified alkaline ammonium sulphate is returned to the extraction bath and may be used to wash the crystallized salts en route. (1,274,998-1,275,000; Aug. 6, 1918.)

**Pyroxyline Composition of Exceptional Durability.**—Camphor-collodion compounds of the ordinary type are usually more or less brittle. Mr. PEPPINO MAJORANA of Louisville, Kentucky, finds that alcohol used in compounding the ingredients gives specially desirable products. He patents a composition within the limits:

|                    | Per Cent  |
|--------------------|-----------|
| Clear collodion    | 75. — 85. |
| Spirits of camphor | 5.5 — 7.5 |
| Gum camphor        | 8 — 10.5  |
| Dye                | 2. — 3.   |

In the manufacture of phonographic ribbons having sound wave lines pressed into both sides, it is claimed that there is no liability of the material to tear or break, even at these areas of minimum thickness. (1,275,063; Aug. 6, 1918.)

FIG. 1.

equalling two tons as at the first, but carrying 1.24 per cent Cu, partly cuprous and partly cupric. Of this, 0.386 tons are passed over scrap iron to recover cement copper, and an equivalent amount of iron is dissolved as  $\text{FeCl}_2$ . The barren solution is reunited to the pregnant leach, 8.5 pounds of chlorine added by

**Starting Sheet Suspension.**—HENRY S. MONTGOMERY and HENRY A. TOBELMANN, of Ajo, Ariz., have found that an electrolytic starting sheet, if hung between the ends of a loop, riveted thereto, will not build up at the edge between the loop ends, but on the contrary, the sheet is dissolved at such a rate that it falls from its support into the tank before any considerable metal has been deposited. In order that the loops and sheet may remain connected it has been found that the connection

FIG. 3

should be made in such a way that there shall be no metal of the sheet between the layers formed by the loop legs; that is, so that a free surface of starting sheet shall always be opposite the area covered by the supporting loop. The various methods of making this connection are illustrated in Fig. 3 and need no description. (1,269,458; June 11, 1918.)

**Ammonia Leaching.**—EARL T. STANNARD, of Kennebec, Alaska, patents a method whereby volatile solvents can be used in the leaching of ores, and extracted in such a manner that large losses in leached residues are avoided. Fig. 1 shows a typical instance of his process as applied to one lot of 600 tons of 1.5 per cent copper ore. He uses a closed leaching tank capable of being sealed and operated under pressure, with a steam inlet at the top and the usual filtering bottom. Approximately 1.1 pounds of ammonia are needed per pound of copper in the charge; in the illustration 125 tons of 8 per cent solution is indicated. The amount of solution varies with the fineness of the ore; a minimum amount being naturally desirable in order to reduce the total mass of liquids to be handled in process. After the rich solution has been drained from the ore, washing is done by introducing steam under pressure from above. This steam penetrates into the bed slowly, being condensed as it reaches cold ore, when the condensate trickles down, effectually washing before it the entrapped rich liquor. In this manner the copper salts in solution are kept ahead of the heated areas, thus obviating the danger of formation of insoluble copper compounds in the leach tank. When the total volume of ore has become permeated by live steam, the condensate ceases to flow—it having previously been added to the original filtrate—and the steam and ammonia it contains is then diverted to the surface con-

denser, where both are liquefied and returned to the new leaching solution. The amount of steam varies as the temperature of the ore, its nature and sizing, the depth of bed and the extraction of the solvent required; in the illustration, the steam is interrupted when the leached residues contain 0.05 pounds of ammonia per ton. This economical point of wastage varies with the relative cost of ammonia and steam. The leached residues are hot and contain but little moisture which readily evaporates when the tank is opened, giving a dry material which is easily handled. The rich solutions are boiled in a still, black oxide of copper being precipitated, ammonia being volatilized and condensed in suitable apparatus, and the boiled-out solution used to the required extent in making up fresh leaching solutions. (1,238,954; assigned to Kennecott Copper Corporation, Sept. 4, 1917.)

**Phosphorus from Molten Slag.**—The electric furnace smelting of a mixture of phosphates, sand and coke, with the accompanying reduction and distillation of phosphorus and its collection under water, has been in successful use for a decade. Mr. H. O. H. WENMAN of Bishop's Castle, England, patents passing molten slag direct from the iron furnace with sufficient silica and coke added, through an electric furnace, thereby accomplishing the old process with a saving in electric consumption of about 90 per cent. The reaction takes place at from 1300 to 1500 deg. C.

**Anode Suspension.**—JULIUS H. GILLIS, of Toronto, Ontario, notes the disadvantages of suspending anodes by upward projecting lugs. These remain as scrap for remelting, accidental breakage is common and they are difficult to cast. Lead suspensions are not desirable owing to the low tensile strength of the metal. Lead-covered suspension materially thicker than the anode cause growth of cathode crystals opposite any projecting portion, rapidly short circuiting the cell. The in-

FIG. 4

ventor discovered that anode connectors of aluminium, somewhat of the shape shown in Fig. 4, overcome most of these difficulties, in that aluminium rapidly forms a continuous deposit of non-conducting salts when immersed in ordinary electrolytes. He casts a small block of copper 9 into the hanger so as to give a good metallic contact between hanger and cathode. (1,267,653; assigned to British America Nickel Corporation, Ltd.)

## Personal

MR. H. W. ALDRICH has resigned his position with the Anaconda Copper Mining Company to become assistant general superintendent of the Inspiration Consolidated Copper Company's plant at Miami, Ariz.

DR. SERGIO BAGNARA, metallurgist of the St. Joseph Lead Co. of Bonne Terre, Mo., has been appointed metallurgical engineer of the Ordnance Department. Dr. Bagnara is on his way to Washington, D. C., but expects to see service in France.

MR. HARRY B. CHAPMAN, formerly manager of the Chapman Engineering Co., Texas City, Texas, is now connected with the Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa.

MR. CHARLES Y. CLAYTON is now with the Bureau of Mines, Pittsburgh, Pa.

MR. E. P. DILLON is now general manager of the Research Corporation of New York. He was formerly manager of the power division, New York office, Westinghouse Electric & Manufacturing Co.

MR. C. E. DRAYER has been engaged as national secretary of the American Association of Engineers, Chicago, Ill., by the Board of Directors.

MR. W. C. EBAUGH has left Salt Lake City for Newark, Ohio, where he will become a member of the faculty of Denison University.

MR. J. H. FENTON, of the Los Angeles office of the Westinghouse Electric & Mfg. Company, has recently been appointed manager of the industrial division of that office, which includes jurisdiction over the Tucson and El Paso offices.

MR. H. M. FREEBURN has resigned as assistant engineer of the Pennsylvania State Department of Health to become associated with the engineering staff of Wallace & Tiernan Company, Inc., New York City, manufacturers of chlorine control apparatus and sanitary engineering specialties. Following his graduation from the Sanitary Engineering course of the Pennsylvania State College, Mr. Freeburn was an instructor at the institution and was in charge of experimental sewage work.

MR. R. R. HENDERSON, formerly chief chemist of the Vreeland Chemical Co., has resigned his position with that firm in order to devote his entire time to consulting practice. He now has his headquarters at Little Falls, N. J.

MR. ROBERT M. KEENEY has resigned as manager of The Ferro Alloy Co., Denver, Colo., to become general manager of The Iron Mountain Alloy Co., Denver, Colo.

MR. WILLIAM KOROTKIN has accepted a position in the engineering department of the Burro Mountain Branch of the Phelps-Dodge Corporation, Tyrone, New Mexico.

MR. J. N. MAHONEY, for 12 years a member of the engineering department, has tendered his resignation from the Westinghouse Electric & Mfg. Company, to open consulting offices in New York.

MR. B. MAGNUS has been commissioned captain in the Engineers Reserve Corps, and is now on active duty. He requests that all communications for him be sent care of Henry M. Toeh, 320 Fifth Ave., New York City.

MR. JOHN C. MERRILL is the successor to the firm of Sul-liger and Merrill, located at 1400 Ilibernian Building, Los Angeles, California.

MR. MERLE G. PETERSON is now connected with the Walter A. Zelnicker Supply Co.'s Chicago sales force at 428 First National Bank Building.

PROFESSOR J. H. RANSOM has been elected professor of chemistry and director of the chemical laboratories of Vanderbilt University at Nashville, Tenn. This university is considered to be the standard for college education in the South and the chemistry department is among the strongest in the university. Professor Ransom brings to his new

duties a wide and successful experience which must prove of advantage to the university and to the scientific education of the South. For a number of years Professor Ransom has been professor of general chemistry in Purdue University, and offered his resignation there just before the close of the school year just ended.

MR. H. J. SEAMAN of Catsauqua, Pa., formerly general manager of the Atlas Portland Cement Co., Northampton, Pa., has been appointed manager of the German-American Portland Cement Co., La Salle, Ill., by A. Mitchell Palmer, Alien Property Custodian.

MR. HENRY STROH has recently been added to the sales force of the Walter A. Zelnicker Supply Co., St. Louis, Mo. Prior to this he was connected with the Elliot Frog and Switch Company.

MR. T. AN. TESCH established on May 1, 1918, an engineering and construction office at Tumba, near Stockholm, Sweden. He will devote himself especially to the construction of modern iron and steel works, electric or non-electric.

MR. C. E. VAN BARNEVELD is in Denver, where he will remain for a time in connection with war-metal for the Bureau of Mines.

MR. CLAUDE C. VAN NUYS has resigned his position as professor of physics in the Colorado School of Mines and has removed to New York City, where he will be physicist for the Air Reduction Co.

MR. C. H. VONBAUR is now vice-president of the T. W. Price Engineering Co., Woolworth Bldg., New York City.

## Current Market Reports

### Non-Ferrous Metal Market

*Monday, August 26.*—Many metals go from producer to consumer via other channels than the open market, so that available supplies are in effect assigned with prices economically fixed and not fluctuating with the demand.

*Aluminium.*—The Government prices on ingots of 90 to 99 per cent Al are \$660 a ton f.o.b. plant in 50-ton lots, \$662 down to 15-ton lots and \$664 down to 1 ton, which prices will be effective for the remainder of this year. Prices per pound for small lots vary from 40 to 45c.; sheet aluminium, 18 ga. and heavier, 42c.; powdered aluminium, \$0.65 to \$3.00, according to mesh.

*Antimony.*—Increase of production costs in the Chinese mines due to present war activities in Asiatic Russia has resulted in a stronger buying demand and limited offerings. The price, duty paid, is now firm at 14% to 14%.

*Chrome.*—High-grade material is bringing a premium, 50 per cent ore selling at \$1.70 per unit.

*Copper.* The price of \$520 per ton has been continued by the War Industries Board for car load lots and 27.3c. per pound for smaller quantities. It is considered better to curtail nonessential consumption to obtain the Governmental requirements than to allow a sufficient price to make lean mines profitable.

|                                |        |          |
|--------------------------------|--------|----------|
| Copper sheets, hot rolled, lb. | \$0.36 | — \$0.37 |
| Copper sheets, cold rolled     | 37     | — 38     |
| Copper bottoms                 | 44     | — 45     |
| Copper rods                    | 36     | — 37     |
| Copper wire                    | 29     | — 30     |
| High brass wire                | 28     | — 29     |
| High brass sheets              | 28     | — 29     |
| High brass rods                | 26     | — 28     |
| Low brass wire                 | 32     | — 34     |
| Low brass sheets               | 32     | — 34     |
| Low brass rods                 | 33     | — 35     |
| Brazed brass tubing            | 37     | — 39     |
| Brazed copper tubing           | 42     | — 44     |
| Seamless copper tubing         | 41     | — 43     |
| Seamless bronze tubing         | 45     | — 46     |
| Seamless brass tubing          | 37     | — 39     |
| Bronze (gold) powder           | 1.00   | — 1.75   |

*Lead.*—The lead market is limited by selling restrictions. Producers must sell at a uniform and pre-arranged price. In car load lots at East St. Louis, the price is \$155 per ton. In New York, jobbers sell in jobbing lots at 8.55c. per pound plus cartage, though the wholesale price is still fixed at 8.05c. Full sheet lead, 10c.; cut sheets, 10½c.

**Manganese:**—Prices remain at \$1.35 per unit basis for better grades.

**Molybdenum:**—The price is \$1.00 per unit for 90 per cent MOS.

**Zinc:** Spelter is advancing. East St. Louis selling at from \$178, to \$182, per ton in car load lots. New York prices range between 9½ and 9¾ c. per pound; sheet zinc, 15c. and zinc dust, 16c. to 20c. per pound in 1600-lb. casts.

**Tin:**—Tin prices are declining, there being no large buyers on the open market and few dealers selling. Straits tin for September and October shipment from Singapore are offered at 79c. per pound subject to permit for consumption. About 3000 tons arrived during the first half of August. Tin for export from England has been quoted at 83c. and Banca at 84c. Spot tin is 88c. Babbitt metal varies between \$1.10 and 70c.; solder (50-50), 73c. per pound.

**Tungsten:**—High grade Wolframite and Scheelite with 92 tin, no copper and low manganese and over 70 per cent WO<sub>3</sub> is quoted at \$24 per unit.

**Silver:**—The Government has set a price of \$1.011 per troy ounce. This advance is due to the great amount of silver necessary to send to India to settle the European trade debit of \$360,000,000. As the world production of silver is only 172,000,000 ounces annually, Great Britain and the United States have been drawing on their silver currency. The Federal Reserve bank notes, our ninth form of monetary exchange, is now being introduced to release this great silver disbursement. Our army in Europe is now being paid in silver also.

#### OTHER METALS

|                                   |         |        |
|-----------------------------------|---------|--------|

### The Iron and Steel Market

No important new regulations have been promulgated since last report for the distribution of pig iron and steel products. The system is regarded as practically perfect, and seems to be entirely satisfactory both to the War Industries Board and to the producers. What is unsatisfactory to both, and also to many buyers, including both jobbers and manufacturing consumers, is that the supplies are not sufficient to stretch to the less essential consumption purposes, let alone to those which are not recognized as entitled to any preference at all.

The whole thing, however, is a matter of viewpoint. In the last analysis it is eminently proper that the conditions viewed in various details should appear unsatisfactory. We are engaged in a great war. The soldier in the front line trench is quite dissatisfied. He should be in what is the enemy's front line trench, but if he were there the enemy's second line would be his objective.

There are set prices for iron and steel products, no competition. Competition is dead. There is the fiercest competition in the United States that has ever been experienced. It is of a different order. The American Navy is what it is to-day because it has always been the field of sharp competition, between men, gun crews, ships and fleets. There is competition between shell factories and forge shops, between forge shops and mills producing shell steel. Shipways launching hulls are competing with engine and boiler makers on the one hand and with steel mills supplying steel on the other. Each branch of each war activity is striving to move faster than others. The way to win the war is to take the view that shipbuilding is behind steel making, or steel making behind shipbuilding, not that the one is ahead of the other. Everything is in the wrong place that is not in the vanguard.

If the consumers whose activities are not particularly helpful in winning the war were receiving a full supply of steel, something would be altogether wrong. The war

activities should be able to consume that steel. It is precisely right that steel should be "scarce" from the viewpoint of the buyer who is accorded little or no preference by the regulations. That is the view taken even by those who experience the deprivation.

All things considered, the rate of steel production is very satisfactory by comparison with the conditions under which steel is produced. In June a rate of ingot production of 43,500,000 gross tons a year was attained. In July, with hot weather, the rate declined to about 42,250,000 tons, which is a smaller decline than usually occurs at this season of the year. August has perhaps developed a slightly lower rate, but better rates than 43,500,000 tons are expected later in the year. With the supply of scrap scant and the quality quite indifferent, with labor far from plentiful, and with multitudinous difficulties confronting furnaces and mills, the rate of production is on the whole very good. The existing ingot producing capacity is probably ratable at more than 47,000,000 tons a year with all conditions favorable but with conditions as they obtain, the lower rate is gratifying.

Demands for pig iron and steel to be shipped abroad, either for direct use by the A. E. F., or for repayment of material borrowed by General Pershing, or for new demands of our Allies, continue to increase. Additional car orders have been placed, together with orders for 200,000 tons of rails. Shell orders have been increasing, shipbuilding is speeding up week by week and new military wants are constantly developing.

The present trend is in the direction of further curtailment in the production of finished steel not directly involved in war work. Sheet mills, which have been operating at barely 60 per cent capacity, may be furnished somewhat less steel in future. The steel allotted to rod mills has decreased somewhat. Standard steel pipe manufacture has been on a somewhat reduced scale and the August distribution to jobbers is less than was expected. Merchant mills are allotted little more steel than enough to fill the higher priority orders, evidenced by the fact that the B-4 priority accorded to jobbers is not sufficient to give them much merchant bar tonnage.

Scarcely any class D steel is developing. The rule is one thing and operations under it are quite another thing. According to the regulations, if a manufacturer has material or manufacturing facilities beyond what is necessary to take care of priority orders and requirements of the preference list, the surplus becomes class D. The manufacturing facilities may be used and the material shipped in connection with a use not accorded preference, provided the manufacturer has the "permit" of the Director of Steel Supply "first had and obtained." The application must be made by the prospective producer, not by the prospective buyer. Apparently there is no harm in applying for permission to do something. One may then avail himself of the permission or not, as circumstances dictate. That is not the view of many steel producers, however, who reason that to apply for a permit to make and ship class D steel represents an admission that the thing can be done, and if it can be done, the War Industries Board may very properly hold the producer to the admission and require that the thing be done, that the steel be shipped for some war use, excuses not accepted. In other words, one may apply for a permit to ship 500 tons of class D steel and receive by return mail a priority order to ship 500 tons. Few permits are applied for and still fewer are granted. Some mills have slight surpluses of odds and ends but will probably use the material as scrap, to swell the production of war steel, rather than flirt with the permit system.

#### ABUSES OF SCRAP REGULATIONS

The very serious abuse of the scrap regulations as regards the purchase and scale of so-called "unguaranteed low phosphorus scrap" at \$34 when the price should be \$29 has been taken in hand in vigorous fashion by the authorities. The scrap committee of the American Iron and Steel Institute has issued a circular letter to all steel makers promising drastic action if the practice is not stopped and stating that existing contracts violating the provisions

should be canceled. The American Board of Scrap Iron Dealers has likewise issued a circular to its own members.

Low phosphorus scrap is No. 2 in the regulations, and three subdivisions are named, "C" being stated to cover "steel knuckles and couplers, rolled steel wheels, railway steel springs, carbon tool steel and material similar in quality and character." For this material \$34 may be paid for use in acid open-hearth furnaces. For ordinary heavy melting steel no more than \$29 may be paid.

The regulations were clearly worded and could not possibly be misunderstood by anyone of average intelligence. A trade had arisen, however, in what was called "unguaranteed low phosphorus scrap," the term being a pure fiction, and material that would hardly grade as heavy melting steel was being bought and sold at the \$34 price, much of it evidently intended for use in basic open-hearth furnaces. These evasions have not been altogether denied by the trade, but the argument has been used that the payment of the premium does not hurt the Government, as its purchases of finished steel products are at set limits. The argument overlooks the important fact that the payment of the premium reduces the profit of the mill, and as the Government is likely to tax the last \$5 of profits 80 per cent, there is ground for arguing that the payment of \$5 extra causes the mill to lose \$1 and the Government \$4.

### Chemical Market

**HEAVY CHEMICALS:**—The markets in general have been extraordinarily quiet, during the last few days in particular. Caustic and soda ash, which may be called the barometers of the trade, have been very inactive with a slight falling off in saccharine. As to dealers' profits in sulphuric, definite statement has been made by the authorities.

**Sulphur:**—The chemically pure floured product is subject to a very wide demand which, it is said, has increased 50 per cent over the normal, in view of which and remembering that the supply has been somewhat curtailed temporarily, some of the interests in the trade believe that this material will shortly see necessarily increased prices. Shipments are said to be coming in more slowly, confirming statements with regard to shortening of stocks. Nevertheless there has been no advance in prices during the week, as quotations continue on the basis of from \$4.35 to \$4.50 per hundred pounds f.o.b. New York.

**Sulphur Chloride:**—Orders for single jugs of this material are being quoted prices as high as 20c. per pound while in larger quantities from 15 to 19 and 20c. is asked. For the material in drums from 7½ to 9c. is the range of asking prices, depending upon the quantity and the buyer. Drums are extra and prices quoted f.o.b. New York.

**Epsom Salts:**—There is a good demand for this product but business lately has been of a very quiet character. Certain large producers have been compelled to withdraw from the market for the present owing to depletion of reserve stocks, but prices asked in other directions continue at from 3.40 to 3.50 f.o.b. New York with prices at the works holding 3c. in bags and 3¼c. in barrels for the U.S.P. material.

**Bleaching Powder:**—It has become practically impossible to locate spot holdings as even directions ordinarily in close touch with sources are themselves unable to accept orders for earlier than September shipment. The last sale reported was for shipment of material in from two to three weeks at 4½c. f.a.s.

**Potassium Permanganate of Potash:**—The market is very quiet with manufacturers continuing to quote 1.75 for the U.S.P. and from 1.30 to 1.50 for certain high-grade technical goods, although there are rumors of purchases at much below these figures.

**Dichromate of Soda:**—This market has seen a slight weakening although large factors state that sales have been consummated right along at 26c. Offerings of 24¼c. f.o.b. works have been made and contracts have been signed at 23¼c. Authorities, however, feel that the market will see a stiffening in a few days. Producers of soda from

the domestic chrome ore are asking 24¼c. The Caledonian chrome is not being imported directly but small quantities are coming in from time to time on vessels which use it for ballast on their return voyages; such quantities are small ton lots, however.

**Calcium Carbide:**—This market continues to hold at 19c. for September shipment, as spot lots are scarce. Exportations are limited by the lack of bottoms.

**Sodium Sulphide:**—Holdings are hard to find and inquiry is strong. Cars of spot material have changed hands at 8c. but offerings are now on the basis of 8½c.

**Carbon Bisulphide:**—Demand is steady with sales being made through the usual channels direct to consumers in most cases. Stocks are said to be sufficient to meet the requirements and prices therefore remain firm at 8c. per pound f.o.b. works.

**Caustic Soda:**—Transactions have been very few with the large inquiry on material rolling toward the Pacific coast on which prices are quoted 4.30 western works. Ex warehouse New York is quoted at 4.15.

**COAL TAR PRODUCTS:**—Very little change has taken place in these items as these markets have also been unusually quiet; saccharine perhaps showing the greatest activity with a slight falling off both in demand and price during the last few days.

**Phenol:**—Various prices are heard and some uncertainty in the trade as to just what the market may be in view of quotations from important directions at from 44 to 46c. and the knowledge that 43 or better may still be done. This latter price is quoted by directions having contracted some time ago and the higher prices quoted above apply to present business. Reports of scarcity are current with the result that prices are rather firm. It is not known that any new export licenses have been granted, the material going forward from time to time being upon licenses which had been revoked and later renewed.

**Benzol:**—Conditions remain the same with regard to offerings in tank car quantities at 23c. with certain directions willing to do business on the basis of 22c. on contract. For material in drums the level of 28c. continues to hold; but in view of the placing of large Government orders there is a general feeling that prices will see an appreciable advance in the Fall owing to a resulting shortage of stocks.

**Saccharine:**—A slight falling off is noted in the prices prevailing at this writing, attributed by some to the rumor that the British Government is to cancel all licenses and prohibit further importations of this product beginning Sept. 15, and another rumor which was heard to the effect that the government contemplated taking over the manufacturing. Largest factors in the manufacture state, however, that they have no knowledge of such intention on the part of the authorities. Soluble material is holding at the level of the last sales reported, 35.50, with insoluble available at 33.00. Very few sales are reported.

**Paraphenylenediamine:**—The demand for this material is fair with the prices showing a slight advance over those last reported, as from 4.00 to 4.50 is now asked depending upon grade and quantity. It is said that new manufacturers are about to enter the field and to produce a material of 99½ per cent. The C.P. product is almost unobtainable.

**Dimethylaniline:**—This market is not active and prices show no change. Supplies are said to be rather plentiful with quotations continuing to be made at 73c. spot, drums extra and nonreturnable.

**Dinitrophenol:**—There is very little of the material to be obtained as the factors in its production are directing their output to Government ends and have none but a very small quantity which may be offered in the open market at from 51 to 52c.

**Aniline Oil:**—Supplies are said to be getting more scarce with the natural result of a firmness noted in the market. From 28½ to 29c. for small lots is asked but on contract 28c. can still be done. In some directions 30 and 32c. are heard for large and small drums respectively.

## General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET, AUG. 26 1918

|                                                   |         |               |         |

| Zinc dust, 350 mesh                    | lb.     | .13 1/2 | .14     |
| Zinc oxide, American process XX        | lb.     | .13     | .14     |
| Zinc sulphate                          | lb.     | .04 1/2 | .06 1/2 |

## Coal Tar Products (Crude)

|                                        |                    |      |       |
|----------------------------------------|--------------------|------|-------|
| Benzol, pure, water white              | gal.               | .22  | .28   |
| Benzol, 90 per cent                    | gal.               | .25  |       |
| Toluol, in tank cars                   | gal. (Fixed Price) | 1.50 |       |
| Toluol, for non-military use, in drums | gal. (Fixed Price) | 1.55 |       |
| Xylol, pure, water white               | gal.               | .45  |       |
| Solvent naphtha, water white           | gal.               | .18  | .25   |
| Solvent naphtha, crude, heavy          | gal.               | .12  | .15   |
| Cresote oil, 25 per cent               | gal.               | .45  | .50   |
| Dip oil, 20 per cent                   | gal.               | .30  | .32   |
| Pitch, various grades                  | ton                | 8.00 | 20.00 |
| Carbolic acid, crude, 95-97 per cent   | lb.                | 1.05 | 1.10  |
| Carbolic acid, crude, 50 per cent      | lb.                | .60  | .65   |
| Carbolic acid, crude, 25 per cent      | lb.                | .35  | .38   |
| Cresol, U. S. P.                       | lb.                | .19  | .20   |

## Intermediates, Etc.

|                              |     |       |          |
|------------------------------|-----|-------|----------|
| Alpha naphthol, crude        | lb. | 1.00  | 1.10     |
| Alpha naphthol, refined      | lb. | 1.50  | 1.60     |
| Alpha naphthylamine          | lb. | .60   | .62      |
| Aniline oil, drums extra     | lb. | .28   | .30      |
| Aniline salts                | lb. | .45   | .45      |
| Anthracene, 80 per cent      | lb. |       | Nominal  |
| Benzaldehyde (f.f.c.)        | lb. | 3.75  | 4.00     |
| Benzenidine, base            | lb. | 1.60  | 1.85     |
| Benzenidine, sulphate        | lb. | 1.40  | 1.45     |
| Benzoic acid, U. S. P.       | lb. | 2.65  | 2.85     |
| Benzoate of Soda, U. S. P.   | lb. | 2.65  | 2.85     |
| Benzyl chloride              | lb. | 2.65  | 2.50     |
| Beta naphthol benzoate       | lb. | 10.00 | 12.00    |
| Beta naphthol, sublimed      | lb. | .85   | .90      |
| Beta naphthylamine, sublimed | lb. | 2.65  |          |
| Dichlor benzol               | lb. | .15   | .20      |
| Diethylaniline               | lb. | 4.00  | 4.50     |
| Dinitro benzol               | lb. | .36   | .38      |
| Dinitrochlorobenzol          | lb. | .40   | .45      |
| Dinitrophenol, alpha         | lb. | .55   | .60      |
| Dinitrotoluol                | lb. | .65   | .75      |
| Dimetaphenol                 | lb. | .55   | .60      |
| Dimethylaniline              | lb. | .70   | .78      |
| Diphenylamine                | lb. | 1.00  | 1.10     |
| H-acid                       | lb. | 3.00  | 3.40     |
| Metaphenylenediamine         | lb. | 1.85  | 2.05     |
| Monochlorobenzol             | lb. | .09   | .20      |
| Naphthalene, flake           | lb. | .20   | .20 1/2  |
| Naphthalene, balls           | lb. | .11   | .12      |
| Naphthionic acid, crude      | lb. | 1.20  | 1.30 1/2 |
| Naphthylamine-sulphonic acid | lb. | 1.50  | 1.10     |
| Nitro naphthalene            | lb. | .45   | .50      |
| Nitro toluol                 | lb. | .55   | .60      |
| Ortho-amidophenol            | lb. | .15   | .20      |
| Ortho-dichlor-benzol         | lb. | .95   | 1.10     |
| Ortho-toluidine              | lb. | .75   | .85      |
| Ortho-nitro-toluol           | lb. | 4.00  | 4.50     |
| Para-amidophenol, base       | lb. | 4.25  | 5.00     |
| Para-amido-phenol, H. Ch.    | lb. | 1.50  | 2.00     |
| Para-dichlor-benzol          | lb. | 1.70  | 1.85     |
| Paranitraniline              | lb. | 1.50  | 1.60     |
| Para-nitro-toluol            | lb. | 3.75  | 4.00     |
| Paraphenylenediamine         | lb. | 2.00  | 2.25     |
| Para-toluidine               | lb. | 4.00  | 4.50     |
| Phthalic acid anhydride      | lb. | .45   | .46      |
| Phenol, U. S. P.             | lb. | 5.50  | 7.00     |
| Resorcin, technical          | lb. | 8.00  | 9.00     |
| Resorcin, pure               | lb. | .88   | 1.00     |
| Salicylic acid               | lb. | .32   | .34      |
| Sulphanilic acid, crude      | lb. | 2.50  | 3.00     |
| Tolidio                      | lb. | .85   | .90      |
| Tolidine-mixture             | lb. | .85   | .90      |

## Petroleum Oils

Crude (at the Wells)

|                       |      |      |      |

## Plant Construction—Catalogs—New Publications

### Construction and Operation

#### Alabama

**WOODWARD.**—The Woodward Iron Co. will build a plant to manufacture steel products principally for Government steamship construction. Estimated cost, \$25,000,000.

#### California

**AZUSA.**—The Aul Fumigating Co. will build a plant for the manufacture of cyanide. Estimated cost between \$100,000 and \$150,000. Irving Dingle, manager.

**LOS ANGELES.**—The City Council voted to permit to the people at the fall election a proposition to vote on \$130,000 bonds for the construction of sewage system and treatment plant at the Wilmington Harbor District. A. C. Hansen, City Engineer.

#### Colorado

**DENVER.**—L. M. Styles, has purchased a site at 4th and Navajo Sts., on which he will build a plant for the manufacture of mica.

**PEARL.**—E. H. Lobdell, will build a 50-ton mill to treat ore from the Wolverine mine.

#### Connecticut

**BRIDGEPORT.**—The Union Metallic Cartridge Co., Railroad Ave., has awarded the contract for the construction of a two-story, 60 x 240 ft., concrete, brick and steel factory, concrete foundation, to the T. J. Pardy Construction Co., 15 Fairfield Ave. Estimated cost, \$35,000.

**HARTFORD.**—The Hartford Rubber Co., Park St., has awarded the contract for the construction of a two-story, 60 x 100 ft., rubber factory on Bartholomew Ave., to J. H. Grozier Co., 721 Main St. Estimated cost, \$35,000.

**HARTFORD.**—Henry Souther Engineering Co., 11 Laurel St., has awarded the contract for the construction of a two-story, 35 x 35 and 35 x 15 ft., brick laboratory to Porteus Walker Co., 13 Forest St., Hartford. Estimated cost, \$15,000. Noted Aug. 15.

**OKAWVILLE.**—The Autotype Co. will build a 14-story, 49 x 110 ft., addition to its factory. Estimated cost, \$20,000. Guion Thompson, 27 West Main St., engineer.

**STAMFORD.**—Baer Brothers, 700 Canal St., has awarded the contract for the construction of a 5-story, 75 x 115 ft., reinforced concrete, brick and steel factory for the manufacture of bronze powder, to Thompson & Binger Inc., 230 Madison Ave., New York City. Estimated cost, \$175,000.

#### Florida

**GAINESVILLE.**—The Gillett Oil Co., 1015 Citizens Bank Building, Tampa, has taken over the plant of the Florida Industrial Corporation and will operate it as a castor oil plant under Government control.

**JACKSONVILLE.**—The American Agricultural Chemical Co., Herald Building, has awarded the contract for the construction of a two-story, 240 x 401 ft., reinforced concrete plant for the manufacture of fertilizer, to the Turner Construction Co., 241 Madison Ave., New York City. Noted Aug. 15.

**TAMPA.**—The War Dept., Washington, D. C., will build a plant to manufacture phosphorus for screening ship and troop equipment, to 26 1/2-kw., electric power. W. C. Lockwood, Hillsboro Hotel, investigating for site.

#### Illinois

**GRANITE CITY.**—The National Enameling & Stamping Co. will build a 1-story, 100 x 200 ft., reinforced concrete, brick and steel lime burning plant. Estimated cost, \$100,000. Engineering Service Corporation, Railway Exchange Building, St. Louis, Mo., engineers.

#### Indiana

**NEW ALBANY.**—The Calumet Fertilizer Co. has awarded the contract for the con-

struction of a 1-story, 100 x 250 ft., reinforced concrete, brick and steel factory, to the Austin Co., 1611 Euclid Ave., Cleveland, Ohio. Estimated cost, \$60,000.

#### Iowa

**GARNER.**—City will build a system of sanitary sewers and a sewage disposal plant. J. G. Thorne, 317 Howes Block, Clinton, town engineer.

#### Kansas

**BAXTER SPRINGS.**—The Hoeker Development Co., Miami, Okla., will build a 175-ton concentration plant and is in the market for mill lumber, roofing, gas engine, belts, sludge and slime tables, drills and air compressors. Estimated cost, \$60,000. M. W. Pysher, superintendent.

#### Louisiana

**MONROE.**—The Republic Gas & Carbon Co., Reading, Pa., will build a carbon plant here.

#### Maryland

**BAITIMORE.**—The Maryland Color Printing Co., Holliday and Hillen Sts., has awarded the contract for the construction of a 6-story, 83 x 120 ft., reinforced concrete addition to its plant to the Consolidated Engineering Co., 243 Calvert Bldg.

**BAITIMORE.**—The United States Public Health Service, will build a hospital building and fumigating plant at Quarantine here.

#### Michigan

**HIGHLAND PARK.**—City will install filter equipment superstructure and piping. Estimated cost, \$75,000. L. C. Whitsett, City Hall, engineer.

**SAGINAW.**—The General Motors Corporation will build a foundry plant for the manufacture of automobile castings to consist of a 163 x 440 ft. foundry, 100 x 400 ft. core building, 110 x 265 ft. cleaning room, 100 x 120 ft. pattern shop and storage building. Estimated cost, \$1,100,000. F. D. Chase, Inc., 122 South Michigan Ave., Chicago, Ill., engineer.

**SAGINAW.**—The Saginaw Malleable Iron Co., Center and Salt Sts., has awarded the contract for the construction of a 140 x 400 ft. foundry, to J. S. Kerns, Detroit, Mich. Estimated cost, \$125,000.

#### Mississippi

**PASCAGOULA.**—The City will equip a sewage disposal plant, with accessory requirements. Estimated cost, \$100,000. F. Johnson, Mayor.

#### Missouri

**BELL CENTER.**—The Bankers Mining Co. has awarded the contract for the construction of a 100-ton concentration plant to A. Jeffcott, Joplin. Estimated cost, \$50,000. The company is in the market for steam engine, boilers, crushers, sludge and slime tables, roofing, lumber, air compressors, drills, belts, pipes and hardware, conveyors, track and ore cars.

**DUEWEG.**—The Silver Plume Mining Co. will remodel its 200-ton concentration plant and is in the market for sludge and slime tables, mill hardware, lumber, drill, ore cans and car track. Estimated cost, \$25,000. H. W. Logan, Danvers, superintendent.

**JOPLIN.**—The Big Elk Mining Co. will build a 250-ton concentration plant and is in the market for sludge and slime tables, crushers, mill hardware, lumber, air compressors and engine, boilers. Estimated cost, \$65,000. L. R. Elester, Kansas City, superintendent.

**KANSAS CITY.**—The Upjohn Co., 22nd and Oak Sts., leased a 3-story building and will install machinery to increase the output of chemicals.

**ST. LOUIS.**—The Johnson Tin Foli & Metal Co., 6030 South Broadway, has awarded the contract for the construction of a 2-story, concrete plant to March Construction Co., Railway Exchange Building. Estimated cost, \$35,000.

**ST. LOUIS.**—The La Cede Gas Light Co., 11th and Olive Sts., will build a 1-story, 200 x 1200 ft., steel plant for the manufacture of munitions. G. B. Evans, engineer.

#### New Jersey

**CAMDEN.**—The Concrete Steel Co., Pennsylvania Building, Philadelphia, Pa., will build a 1-story, 50 x 120 ft., addition to its plant at Delaware Ave. and Pearl St.

**PATERSON.**—The Mazzarella Piece Plying Co., 176 Sheridan Ave., has awarded the contract for the construction of a dye house to Stephen Meshier & Son, 92 Albion Ave. Estimated cost, \$4000.

**TREREN.**—The Shaw Pottery Co., Park Ave., will build a 1-story, 35 x 60 ft., addition to its plant.

#### New York

**BUFFALO.**—The Lumen Bearing Co., 167 Lathrup St., will build a 1-story addition to its brass foundry. Estimated cost, \$5000.

**BUFFALO.**—The National Aniline & Chemical Co., Edgewood Arsenal, has awarded the contract for the construction of a 1-story, 40 x 52 and 80 x 80 ft., reinforced concrete, brick and steel plant on Buffalo River, to J. W. Cowper Co., 44 Fidelity Building. Estimated cost, \$75,000.

**BUFFALO.**—The Prest-O-Lite Co., 206 Amsterdam Ave., New York City, will build a plant on Hopkins St. and Colgate Ave., here which will consist of four units.

**CORNING.**—The Corning Glass Works will build a 3-story, 60 x 120 ft. addition to its plant on Walnut St.

**ROCHESTER.**—The Symington Anderson Co., Cutler Building, will build a 1-story, 40 x 118 ft., addition to its plant on University Ave., for the manufacture of guns. Estimated cost, \$15,000.

#### Ohio

**BUYCRUS.**—The American Clay Machinery Co., will build a 1-story, 100 x 250 ft., reinforced concrete, brick and steel factory. Estimated cost, \$60,000.

**CLEVELAND.**—The American Bronze Honor Roll Co., 944 West 23rd St., New York City, will build a 2-story, concrete and brick factory here. Estimated cost, \$25,000.

**CLEVELAND.**—The Buckeye Bronze Manufacturing Co., 1807 Columbus Road, will build a foundry.

**CLEVELAND.**—The Central Brass Co., 6200 Cedar Ave., has awarded the contract for the construction of a 1-story, 35 x 72 ft., reinforced concrete and brick foundry at 6203 Cedar Ave., to Munk Gibbons, 5309 Prospect Ave. Estimated cost, \$7500.

**CLEVELAND.**—The City has authorized the Director of Public Utilities to expend a sum not to exceed \$100,000 for chemicals for the Division of Water.

**CLEVELAND.**—The Var Oil & Paint Co., 929 Schofield Building, has awarded the contract for the construction of a 1-story, 45 x 100 ft., reinforced concrete, brick and steel factory to the Austin Co., 16112 Euclid Ave. Estimated cost, \$25,000.

**JOHNSTOWN.**—The city will build a garbage disposal plant and sewage disposal plant. Estimated cost, \$75,000. J. W. Cramer, city clerk.

**LORAIN.**—The City has awarded the contract for the construction of filter bottoms and manifold castings for waterworks improvements, to the Pittsburgh Filter Co., Farmers Bank Building, Pittsburgh, Pa. Estimated cost, \$100,000.

**TOLEDO.**—Maternity & Childrens Hospital, will build a 1-story, 45 x 125 ft., reinforced concrete and brick hospital on Summit St., to include a pathological laboratory. Estimated cost, \$100,000. G. E. Rheinfrank, 601 Gardner Building, engineer.

**TOLEDO.**—The Toledo Furnace Co., Front St., will build a foundry, two factory buildings and a laboratory, reinforced concrete, brick and steel. Estimated cost, \$100,000. F. Warner, 768 Hippodrome Bldg., architect.

**WARREN.**—The International Steel Tube & Rolling Mills, will build six rolling mills and steel tube mills. Estimated cost, \$500,000.

**YOUNGSTOWN.**—The Struthers Furnace Co., Bridge St., has awarded the contract for the construction of a slag crushing plant, capacity 500 tons, to Eaker, Dunbar, Allen Co., Union Arcade, Pittsburgh, Pa.

#### Oklahoma

**CARNRY.**—City will build a gas plant. Estimated cost, \$1500. Address the Mayor.

**DOLTHAT.**—The Forth National Lead and Zinc Co., will build a 250-ton concentration plant and is in the market for motors, engines, boilers, sludge tables, belts, lumber, mill hardware, drills, air compressors and conveyors. Estimated cost, \$65,000. J. H. Morris, superintendent.

**McALESTER.**—The City will build a sewage disposal plant. Estimated cost, \$110,000. J. M. Gannaway, City Clerk.

**MIAMI.**—The Lead Roy Mining Co., will remodel and enlarge its 250-ton concentration plant and is in the market for gas engine, sludge and slime tables, crushers, belts, air compressors, drills and mill hardware. Estimated cost, \$25,000. R. H. Elkins, Miami, superintendent.

**PICHER.**—The Cortez Mining Co., Miami, will build a 250-ton concentration plant and is in the market for sludge and slime tables, gas engine, lumber, mill hardware, crushers, air compressors, conveyors and belts. Estimated cost, \$65,000. W. T. Landrum, superintendent.

**PICHER.**—The Hidden Treasure Co., will build a 350-ton concentration plant and is in the market for sludge and slime tables, motors, air compressors, crushers, lumber, hardware, roofing and conveyors. Estimated cost, \$65,000. C. S. Campbell, Baxter Springs, superintendent.

**QUAPAW.**—The Red Rose Mining Co., will build a 200-ton concentration plant and is in the market for crushers, lumber, mill hardware, belts, pipe, air compressors, ore cars, track and conveyors. Estimated cost, \$65,000.

**ST. LOUIS.**—The Kansas Line Mining Co., will build a 300-ton concentration plant, and is in the market for sludge and slime tables, lumber, mill hardware, roofing, engines, belts, air compressors, crushers. Estimated cost, \$65,000. W. A. Meese, superintendent.

## Oregon

**PENDELTON.**—The City will build a septic tank for the sewerage. Estimated cost, \$25,000. Geary Kimbrell, city engineer.

**WALWALA.**—The City will build a sanitary trunk sewer and sewage disposal plant.

## Pennsylvania

**GREENVILLE.**—The Sharon Waterworks Co., will extend its filtration plant and beds at the pumping station where a 5,000,000 gallon pump will be installed.

**LYKEN.**—The American Briquet Co., Drexel Building, will build a 1-story, 50 x 225 ft., briquetting plant. Estimated cost, \$200,000. Kern Dodge, 1512 Morris Building, architect.

**PHILADELPHIA.**—Wm. Cramp & Sons, Ball and Beach Sts., has awarded the contract for the construction of a 1-story, 50 x 220 ft., brick and steel coppersmith shop on Richmond and Morris Sts. to Asa Moore, Bulletin Building. Estimated cost, \$31,000.

## South Carolina

**COLUMBIA.**—The City will build an additional coagulating basin on the hill east of the old basin, increasing the total capacity to 12,000,000 gallons of filtered water daily. T. K. Legare, city engineer.

## Texas

**CARLEBAD.**—City will build a sanitary sewage disposal plant for the State Tuberculosis Sanatorium. J. B. McKnight, superintendent.

**DALLAS.**—The Trinity Products Co., will rebuild its guerciton plant, recently destroyed by fire entailing a loss of \$100,000.

**ELECTRA.**—City has awarded the contract for the construction of a sewer system and a 1000-gal. water tank. Estimated cost, \$130,000. D. J. Howell & Son, Union Trust Building, Washington, D. C., engineers.

**HILLSBORO.**—City will build a sewage disposal plant. Estimated cost, \$25,000.

**HOUSTON.**—The Empire Gas & Fuel Co., will build an oil refinery on ship channel.

**LAREDO.**—The Laredo Water Co. will improve the waterworks and install a filtration plant.

**SAN ANTONIO.**—Geo. B. Ellgestern, San Antonio, and H. H. Todd, Gainesville, will build an oil refinery. Estimated cost, \$350,000.

## Virginia

**ALEXANDRIA.**—The Alexandria Water Co., will build a gravity filtration plant, daily capacity 2,000,000 gal. Estimated cost, \$130,000. D. J. Howell & Son, Union Trust Building, Washington, D. C., engineers.

**CLINCHFIELD.**—The International Coal Products Corporation, 24 Broad St., New York City, will build a plant for the manu-

facture of carbocool. The Clinchfield Carbocool Corporation being organized will operate the plant to distill coal to recover toluol, benzol, naphtha, ammonia, creosote, etc. and manufacture residue into fuel briquets. The plant is under Government supervision.

**RICHMOND.**—The Chesapeake & Ohio Ry. Co. will build a 100 x 400 ft. plant for the manufacture of nitrogen, oxygen, acetylene and other gases. K. T. Crawley, industrial engineer.

**RICHMOND.**—The Chesapeake & Ohio Ry. Co. has awarded the contract for the construction of a 1-story, 52 ft. 10 in. x 244 ft. brick and steel brass foundry, to Arnold & Co., 105 South La Salle St., Chicago, Ill. Estimated cost, \$50,000.

## Washington

**SEATTLE.**—The Kilbourne-Clarke Manufacturing Co., 24 West Connecticut St., has awarded the contract for the construction of a wireless-manufacturing plant consisting of a 1-story, 100 x 300 ft. machine shop, 2-story, 60 x 100 ft. store house, 1-story, 60 x 100 ft. laboratory, and a 2-story, 60 x 60 ft. office building, at 3450 East Marginal Way, to Fred Woodman, Seattle. Estimated cost, \$80,000.

## West Virginia

**LINN.**—The Monongahela Valley Traction Co., Parkersburg, will build a gas-producer plant.

## Wisconsin

**CUBA.**—The National Zinc Ore Separating Co., will build an acid plant. C. Barker, superintendent.

**NEW DIGGINGS.**—The Skinner Roaster Co., Benton, will build an acid plant to be operated under government supervision. Estimated cost, \$750,000.

## Canada

### British Columbia

**VANCOUVER.**—The Dominion Forestry Service, Journal Building, Ottawa, will build an aeroplane spruce testing laboratory, jointly with the University of British Columbia and the Provincial Government. E. H. Campbell, Journal Building, Ottawa, director.

**VANCOUVER.**—J. W. McFarlane, 1053 Nelson St., will build a fertilizer plant.

## Ontario

**BRAMPTON.**—The City will build a sewage disposal plant. W. M. Treadgold, town engineer.

**KIRKHAM LAKE.**—Wright Hargraves will install a mill at his mine.

**PEMBROKE.**—The Thomas Hink Co., will rebuild its munitions plant recently destroyed by fire, entailing a loss of about \$200,000.

**WINDSOR.**—City will build a filtration plant.

**WINGHAM.**—The Farmers Fertilizer Co. will build a fertilizer plant. Estimated cost, \$8000.

## Quebec

**AMOS.**—The Penn-Canadian Mining Co., Cohasset, Ore., will build a 30-ton concentration plant. B. Nelly, manager.

**LEVIS.**—The city will build a filtration plant. Estimated cost, \$100,000. Edouard Hamel, St. Peter St., engineer.

**VERDUN.**—The British Munitions Co., Ltd., Kings Park, has awarded the contract for the construction of an addition to its shell factory, to E. G. M. Cape & Co., Ltd., 10 Cathcart St. Estimated cost, \$30,000.

## Industrial Notes

**THE METALS DISINTEGRATING CO., INC.**, announces the removal of its offices from South William Street to 82 Broadway, New York City.

**THE METAL & THERMIT CORPORATION'S** Toronto office is now at 15 Emily Street.

**THE DEARBORN CHEMICAL CO., Chicago**, has inaugurated a special sales department for the manufacture and marketing of a number of specialties. One is a rust preventive known as No-Ox-Id, to keep metal parts or finely finished surfaces of the completed machines free from corroding. Another specialty is a cutting oil for use in metal cutting, quenching oils for heat treating, drawing oils and Dearboline, a preparative for cleaning machined parts of emery or grease.

**THE SARCO CO., INC.**, New York City, has opened a new office in Atlanta, Ga., in the Healey Building under the management of C. R. Dunwoody.

**THE JONATHAN BARTLEY CRUGIBLE CO.**, Trenton, N. J., had a fire in Plant No. 2 recently but they wish to announce that all business will be taken care of as though nothing had happened and orders will be delivered as specified with very few exceptions. Arrangements have been made and orders placed for the necessary machinery and equipment and the company expects to be in full operation under its own roof by November 1.

**THE LINCOLN ELECTRIC CO.**, Cleveland, Ohio, has taken an order from the Ordnance Department for 53 150-amp. arc welding machines which will be in demand in connection with portable machine shops carried on motor trucks.

**THE AKTIEBOLAGET FORJUS SMÅLVERKS** Co. proposes to build two electric iron-smelting furnaces this summer, which will make a total of three. The company's power is secured from the Forjus waterfall, power is not used from the Forjus waterfall.

**THE CONNELLSVILLE FOUNDRY, MACHINE & STEEL CASTINGS CO.**, iron and steel castings and special machinery, has discontinued the sales office formerly maintained at 801 Park Building, Pittsburgh. All correspondence should be addressed to the general office at Connelville, Pa.

**THE MCKINNEY STEEL CO.**, Cleveland, Ohio, is erecting four open-hearth furnaces of 65-ton capacity and two more soaking pits, making a total of 16 open hearth furnaces.

**THE CHICAGO PNEUMATIC TOOL CO.** announces that contract has been let and work started on the erection of an up-to-date addition to their Cleveland plant, which is planned to double the present output. It is expected that the work will be completed on the building itself about November first. The necessary equipment has been ordered and it is believed will be delivered and ready for installation about the time the building is completed so that the additional production contemplated will be available very soon thereafter.

**THE RADIUM ORE SAMPLING CO.** announces the completion of a \$12,000 custom sampler at Montrose, Colorado, for the sampling of such ores as uraniferous and concentrates. The plant is equipped particularly for the careful handling of carnotite. The company does not assay, purchase or deal in ores or their products.

**THE BOOTH-HALL CO.**, 565 West Washington Blvd., Chicago, Illinois, has contracts for building Booth-Hall electric steel furnaces for the following companies: Consumers Steel Company, Chicago, Illinois, three 3-ton electric open hearth furnaces, and for the Ecorse Foundry & Machine Company, Ecorse, Michigan, one 3-ton furnace for producing steel castings.

**T. AN. TESCH** has taken over the Aktiebolaget Elektrometall which holds the patents on electric furnaces for pig iron now in operation in Sweden and other countries. He is desirous of getting in communication with American concerns contemplating the construction of modern iron and steel plants, electric or non-electric.

The newly formed **NORDBOTTENS JÄRNVERKS AKTIEBOLAGET** will construct a new plant at Lulea in northern Sweden consisting of 1 or 14 electric blast furnaces, corresponding charge works, hot metal plants, and houses for officers and employees. The necessary power will be contracted from the Swedish government at the rate of 1000 kw. The plant is controlled by the owners of iron and steel plants in central Sweden for the purpose of procuring electric pig iron to be refined at their respective works or be obtained from the Lapidland district. The plant which is being designed by T. An. Tesch will be one of the world's largest electric pig iron producers.

## New Publications

**THE JOURNAL OF THE AMERICAN CERAMIC SOCIETY** Volume 1, No. 1, with date of January, 1918, has recently appeared. The Journal is published by the members of the American Ceramic Society and takes the place of the volume of transactions containing the papers presented at the annual meetings. By reason of the high standard of the American Ceramic Society the new journal may be expected to take first place as the exponent of the arts and sciences applied to silicate industries. George H. Brown, Rutgers College, New Brunswick, N. J., is editor.

### Miss Liberty Is On the Wire

SUPPOSE you were sitting safe and comfortable at your desk—busy of course, but nevertheless very safe and comfortable compared with a night raider in No Man's Land—suppose you were sitting there and your 'phone should ring and your operator should tell you that "Miss Liberty is on the wire." You would be interested, wouldn't you? And then if a calm, firm voice should say "Hello, this is LIBERTY speaking; billions of dollars are needed, and needed NOW"—what would your answer be? Would you feel embarrassed? Would you halt or stammer? Would you be too surprised to answer? Or would you speak up promptly as though answering a call you were expecting?

Beginning September 28 and continuing for three weeks, Liberty is going to speak throughout the length and breadth of the land, and her message is going to be the same everywhere—"Billions of dollars are needed, and needed NOW!" Through the instrumentality of the colored supplement which accompanies this issue of CHEMICAL AND METALLURGICAL ENGINEERING we are trying to aid Uncle Sam in getting a connection with every loyal American. Literally and in fact, Liberty has a long-distance call in for YOU from France. Have you the answer ready?

### Win-the-War Meetings for Fourth Liberty Loan

WE PUBLISH on advertising pages 310 and 311 the announcement of a plan for securing the organized coöperation of all employers of labor in the promotion of the Fourth Liberty Loan. We have given the subject valuable space because we deem it worthy of attention. In view of the fact that it has potential consequences far beyond the success of the loan, or even the winning of the war, we have no hesitancy in urging employers to act upon the suggestions there made.

It is well known that nothing is so effective in securing hearty coöperation in an organization as a feeling of personal responsibility among its members. Nothing is so potent for harmonious achievement of big results as a sense of personal pride among those who make the results possible. The tremendous impetus which Mr. Schwab has given to shipbuilding is due largely to a recognition of these facts; and he has accomplished the result by coming in personal contact with the workers and inspiring them with his own sense of the importance of their work in winning the war. Every employer, can, in like manner, be a leader of his own group of men and a center of influence that cannot be

overestimated. The means to this end is one or more win-the-war meetings of the employer with his employees; and the way in which the plan can be carried out systematically is described in the program booklet mentioned in the announcement. If the plan proves effective for the immediate purpose of promoting a Liberty Loan, why may it not be equally so for all industrial purposes after the war? The idea is worth a trial.

### Rehabilitating Wounded and Crippled Soldiers

THE casualty lists are coming in fast and among the severely wounded there are many who will return with defective equipment in the way of legs and arms. The Government has very wisely planned to avoid, if possible, the pension errors of the days which succeeded the Civil War, and to provide in the place of them the greatest measure of rehabilitation of those that are crippled, so that they may take their places in the community. It is a bad thing to encourage idleness.

We must get over all prejudice against crippled men as a class and it behooves us to find places for those who have been physically injured but who are willing and able to work. Artificial legs and arms have been remarkably developed and we shall address ourselves for the present to a consideration of the industrial employment of one-legged and one-armed men. The blind belong in a different category.

Artificial legs made of hollow willow and leather are so articulated that a man with even two stumps can walk rapidly and for long distances. Physically, a great deal depends upon the stump. Most of these are easy to fit but occasionally there is one that always gives trouble. While a man with one or two wooden legs would seldom be an ideal porter or wheelbarrow operator, usually he can stand up and walk and do a man's work. Again, the one-armed man, properly fitted, is far better off than he used to be. Artificial arms are designed to meet special purposes and it is surprising the number of tools with which these may be equipped. They are not made to look like normal limbs. Some of them are wicked looking members, but are nevertheless remarkably efficient instruments. For ordinary occasions the cripple is provided with a "dress arm" which is an imitation of a normal arm and gloved hand.

Of course it all depends upon the man. There was an Irish lad who lost both legs, his left arm and all the fingers of his right hand in the great blizzard of '86 in New York. When he came out of the hospital they sent him to the poor-house. He told the authorities that if they would support him for a year while he was getting the education he needed he would take care of himself, but if they wouldn't he was resolved to live to be ninety and to make them take care of him all the time. They let him have his way and now he is president of a large bank in Minnesota. He drives his own automobile and even lights his cigar when he smokes. A man with such resolution is bound to succeed. We can't get that kind very often. Some men, as soon as they lose a member, proceed to become self-pitying nuisances, and of these not one in a hundred is worth his salt. But more often, it is said, men with artificial limbs develop an unusual quality of patience. They stick tighter than others to the problem in hand because

they have had the training in patience as grown men to learn the art of using artificial limbs. Their employment is especially indicated in working at processes that need careful watching.

The American Red Cross has undertaken a rehabilitation institute for men injured in industrial and other accidents, taken from the hospitals. They are easily placed at present. But the time is near when such men will be coming out by the thousand. They must be employed if an unwholesome and bad situation is to be avoided. We therefore recommend to our readers that they look about their establishments and make note of the places where returned crippled soldiers may be employed. The records should be constantly studied and made available when the time comes for us to take care of our heroes and to make life worth while to them.

### Change in Meeting of Electrochemical Society

WE ARE advised as we go to press that the American Electrochemical Society has been obliged to change the place of its Fall meeting from Princeton University to Atlantic City, due to the fact that the War Department has taken charge of the University. The meeting will be held as scheduled, Sept. 30 to Oct. 2, with headquarters at the Hotel Traymore.

### Wanted: Information on Blast-Furnace Smelting

IN THE present issue appears a paper on slag control in the iron blast-furnace in which is elaborated the practical applications of the author's slag-viscosity tables recently published by the Bureau of Mines. The thesis advanced is most important; it is that the chemical reactions in the smelting zone depend upon the "active range"—the interval between the temperatures of entrapment and escapement of iron globules in the slag—and that the fuel consumption of the blast-furnace varies directly with the temperature where the iron works itself free from the slag bath. Obviously a slag with a wide active range and yet labile at a relatively low temperature is the one desired in these days of actual and prospective coke famine. The slag-viscosity tables enable the metallurgist to select scientifically the optimum composition fitting his slag-forming ingredients.

This rather novel conception of furnace action has much to commend itself to the theorist speculating upon the reactions proceeding in the smelting zone of the blast-furnace. It throws welcome light upon the reactions of carburization and silicification and may explain the peculiar characteristics of electric pig iron. But ready acceptance may be somewhat delayed on at least one consideration which merits close attention.

Feild's conception of slag action rests upon the assumption that the molten iron is imprisoned in the just-forming slag when viscosity of the latter reaches a value of approximately 10. For the time one may readily accept the oft-repeated statement that the reduction of iron oxide attains completion quite high in the furnace shaft at a low temperature (possibly 800 deg. C.). The present hypothesis implies that carbonization and sulphidation of the spongy mass should also proceed

at about the same temperature. At 1135 deg. C. the austenite-cementite eutectic melts, and with the settlement of the charge it is superheated and readily dissolves any excess metallic constituent. Therefore at 1400 deg. C., the approximate temperature at which the slag reaches a viscosity of 10, the iron has doubtless all fused into fiery drops, and it is very difficult to see how this liquid metal can become trapped in the slowly moving slag; any hardly expects water bubbles to be absorbed in warm tar. Oozing slag certainly will engulf solid fragments, but can it absorb drops of thin liquid?

However one may feel about the "trapped iron" hypothesis, a consideration of the subject opens up most interesting questions on carbonization and sulphidation reactions, on the mechanism of slag formation, on the physical characteristics of many oxides at high temperatures, on the temperature-concentration equilibrium of many important reactions, and on the relation of viscosity to reversible reactions at interfaces. The solution of these cannot fail to be most fruitful in tangible results to scientists as well as works-metallurgists. It is to be hoped that the Bureau of Mines may not only continue the attack upon such fundamental lines, but endeavor to initiate and coordinate individual effort on the part of investigators in many university and research laboratories.

### Ship Losses and Ship Construction

ACCOUNTS of the performance of shipyards are likely to create an unduly favorable impression as to the extent to which the destruction of vessels by submarines is being met. Many of the reports published are more or less fragmentary, frequently referring to the performance of a single week. Launching of hulls has lately exceeded by a large margin the actual completion and delivery of vessels. The production of ship plates has greatly exceeded the quantity that has actually gone into hull construction. Ship construction by the United States or the United Kingdom has sometimes been compared with the vessel losses of the same countries, whereby there is left out of the reckoning the important item of losses by neutrals being far in excess of their vessel construction. Finally, vessel losses are reported in gross register tons while vessel construction is reported in deadweight tons, while roundly speaking it requires about 125 tons deadweight to be built to make up for 100 gross tons lost. The public mind has been confused by the inadequacy of the presentations and the net result of the confusion is to create an impression that combating the submarine by new construction has proceeded farther towards success than is really the case.

The total of allied and neutral vessel losses through enemy action and marine risks since the war began are as follows, in gross tons, including 182,829 tons of Allied shipping interned in enemy ports at the opening of the war:

| Year                | Gross Tons |
|---------------------|------------|
| 1914 .....          | 681,363    |
| 1915 .....          | 1,724,720  |
| 1916 .....          | 2,797,866  |
| 1917 .....          | 6,623,623  |
| 1918 (Seven months) | 2,396,590  |
| Total .....         | 14,224,162 |

Thus the losses have amounted to almost 30 per cent of the world's merchant marine and obviously it is no small task to replace the tonnage. Now, what was the impression created in the average mind by the announcement made in Washington September 4 by the Shipping Board, that shipbuilding in the United States in August broke all records for any country for a month? A very favorable impression, no doubt. The record, however, was of 340,145 tons deadweight of vessels completed, that breaking the American record of 263,571 tons in May, and the British record of 295,911 tons in June. It compares, moreover, with a January output of 88,507 tons by the United States and 37,852 tons by the United Kingdom. The proper conception is that if American shipbuilding in August broke the records, that is so much the worse for the records.

The record of 340,145 tons deadweight completed by shipyards in the United States in August represents no more than about 280,000 gross tons, for comparison with the gross tonnage of vessels lost. At this record rate it would require 50 months for the shipyards of the United States to make up for the vessel losses from the beginning of the war to August 1, 1918. If our August tonnage broke the British record, the indication would be that the British contribution would not be sufficient to cut the time in half.

The Shipping Board began operations in August, 1917. From the beginning to August 1, 1918, the deliveries on its account have been 245,700 tons deadweight of contract vessels and 1,326,156 tons of requisitioned vessels, making a total of 1,571,856 tons deadweight, equivalent to less than 10 per cent of the total losses of 14,000,000 gross tons.

The purpose of these comparisons is merely to show that the job of replacing vessel losses is still to be done. The facts that Great Britain broke her record as lately as last June, and with only 295,911 tons, and that the United States broke her record as lately as August, with only 340,145 tons, show that the job has only been fairly undertaken.

A great deal of information as to what is required in order to build ships has been obtained. For instance, when we severed relations with Germany in February, 1917, we thought steel plates were unobtainable and directed our attention to wooden hulls because we had a great many trees. The wooden-ship chimera died a hard death. The condition for weeks past has been that plate mills are delivering, for account of shipbuilding in the United States, a quantity equal to 650,000 tons deadweight of vessels per month, yet 340,145 tons deadweight of vessels completed in August, barely more than one-half as much, broke the record, and some of the vessels were not steel at that. The launchings in July had been 631,944 tons. Plates, of which 18 months ago we thought we had none available, are in plentiful supply. The bottle-neck is equipment, engines, boilers and a thousand and one other things, as the Director of Shipbuilding plainly and frankly stated recently. The job lies before us and the speeding-up still needed is chiefly on the part of shops all over the country that must furnish engines, boilers, cranes and all sorts of equipment of a dozen other descriptions with which to furnish the hulls.

## Readers' Views and Comments

### Science and the German Language

To the Editor of Chemical & Metallurgical Engineering

SIR:—Anent your most interesting editorial on the use of the German language at present, might it not be well to allow the study of German, stamping on every German page the following:

This language has some admirable characteristics but it has certain notable defects such as lack of any true word for gentleman, sportsman or sincerity.

In this connection, we might say that the German word for sportsman is simply a Germanized form and is pronounced *Schporhtman*; the word for gentleman is *Herr* which means lord or master; the word for sincerity is *Aufrichtigkeit* which means uprightness. These are poor, lame substitutes for our words and both in denotation and connotation have quite different meanings.

CHEMIST.

### Organic Reagents for Research Purposes

To the Editor of Chemical & Metallurgical Engineering

SIR:—I am interested in the letter of Dr. Mees of the Eastman Kodak Co., relative to their manufacture of organic chemicals. In this connection your readers will doubtless be glad to know that the Research Laboratory of Chicago is principally engaged in the manufacture of such products. We are now making in small quantities a series of organic reagents and will begin work in the near future on a series of acridine dye-stuffs which have proved successful in chemotherapy.

G. HEYL.

Chicago, Ill.

### Evaluation of Zinc Dust

To the Editor of Chemical & Metallurgical Engineering

SIR:—In looking over my copy of CHEMICAL & METALLURGICAL ENGINEERING of July 1, I note the reprint of my paper on the Evaluation of Zinc Dust, read at the last meeting of the American Society for Testing Materials. I wish to direct your attention to two errors which appeared in this paper as follows:

1—The correction tube as shown on page 33 of your magazine for July should not be closed at the bottom. The accompanying sketch will show this in its correct form.

2—At the bottom of the first column on page 33 the sentence beginning, "The temperature change, on the other hand, . . . according to Boyle's law," should read, "The temperature change, on the other hand, . . . according to Charles' law."

I suggest that you make these corrections in an early issue of your magazine in order that your readers may have no misunderstanding regarding the article.

LOUIS A. WILSON.

Palmerton, Pa.

### Recovery of Molybdic Acid for Steel Mills

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have just read the article on "Recovery of Molybdic Acid for Steel Mills" in your issue for Aug. 15, 1918. This article in all its essentials is a word-for-word copy of an article of mine published in the *Journal of Industrial and Engineering Chemistry*, vol. 7, page 213.

W. D. BROWN.

Carnegie Steel Co., Duquesne, Pa.

To the Editor of Chemical & Metallurgical Engineering

SIR:—I am very much surprised to learn that Mr. W. D. Brown of the Carnegie Steel Company had previously published the note on the "Recovery of Molybdic Acid for Steel Mills." The information which I contributed to your journal some time ago was given me by another chemist and I had no knowledge that it had ever been published or that it was a copy of another article. If this was taken from Mr. Brown's publication I wish to express an apology for seeming to publish the material as my own.

W. H. LYNAS.

Columbus, Ohio.

### Research Preparedness in the Zinc Industry

To the Editor of Chemical & Metallurgical Engineering

SIR:—The interesting letter of Mr. J. H. Hastings, commenting upon and accenting my paper in your issue of July 1, presents some views as to detail construction of retorts and charging that may be good but are not those I had in mind.

The briquetting of zinc charges appeared to have been about as well worked out by me two years ago as was desirable, but since then I have run across a process that may displace all pressing so far as roasted charges are concerned, and cut the cost of the act from one dollar per ton to perhaps 25 cents. This process will not do, however, for the lime-process briquet which I feel will be the briquet of the future, for several reasons.

Mr. Hastings makes the statement that because of using the vertical retort the maintenance charges will increase, but gives no reasons. My conclusions would be that maintenance would be less, because there would be no sagging of retort, and less slag action on vertical sides than on a horizontal bottom.

The savings that can be made in zinc distillation are indeed large, but so radical in action as to defer the attention of distillers until the electrothermic furnace using the lime process in the hands of mine owners and waterpower companies in the Northwest, makes it necessary for them to economize or go out of business.

Comments like those of Mr. Hastings show that some of us are thinking, which outside of quick dollar-making is almost a lost art.

PARKER C. CHOATE.

A tin-smelting plant has lately been erected at Leeuwpoot (Transvaal), and it is understood that operations will begin shortly.

## Western Chemical and Metallurgical Field

### Cyanide.

CANADIAN mills using cyanide are furnished their solvent by the Cassel Cyanide Company, Ltd., of Glasgow, Scotland, at a price which varies from month to month and which is based on the rates which the maker pays for the raw materials. The ruling price for the chemical to the Canadian mills during the early part of 1918 was in the neighborhood of \$0.25 per pound (plus duty) for standard cyanide titrating 100 per cent KCN, delivered to the nearest railroad station. The sodium cyanide normally supplied titrates to the equivalent of 130 per cent KCN or more, but the price to consumers is calculated on the basis of 100 per cent KCN, as noted above. In the early part of 1917 a shortage was threatened on account of a prospective labor shortage, the tendency of the military authorities in Great Britain then being to overlook all peaceful industry and sacrifice everything for the vigorous prosecution of the war. On the proper representation being made in London by the combined Canadian, South African and Australian governments, all these difficulties were removed, and now, so long as ships are available to cross the Atlantic, no further trouble need be anticipated.

In the western United States there is plenty of cyanide available on the market in the form of one-ounce eggs. Comparatively little is taken by mills, gold and silver cyanidation being on the wane, for well-known reasons. Much more is used in gas-fumigation of citrus trees. The United States supply is furnished almost exclusively by Roessler & Hasslacher Chemical Co., from their Perth Amboy plant. In the Mexican markets cyanide from both the American and Glasgow firms is being offered at reasonable prices.

### Town Planning in Copper Camps.

Some managers can readily see the advantage of retaining contented workmen after asking their account-

FIG. 1.—THE PLAZA

ant to tell them the cost of the labor turnover. Then they are almost ready to become paternalists in an effort to keep a man after they have got him. Others are more obtuse, even to requiring I. W. W. propaganda to drive home the fact that only a "floater" will inhabit an old-fashioned construction camp.

An enlightened view, in fact the only tenable view, of housing conditions has been taken by the management

of the New Cornelia Company when developing their oxide mine and leaching plant at Ajo, Arizona. Situated in the midst of an absolute desert at the southern edge of the state, the natural surroundings are as unenticing and the heat of summer as enervating as can possibly be imagined. Yet their operations, calling for the highest skill in both mining and metallurgical departments, demanded at all times a stable group of expert workmen.

An idea of how well the effort to counteract the natural unattractiveness of the surroundings has suc-

FIG. 2.—HOUSES FOR WORKMEN

ceeded may be had by the accompanying view of part of the plaza.

Water is pumped from wells many miles distant, and is therefore at a premium, yet enough can be spared for the needs of this beauty spot which forms the community center, surrounded on all sides by colonnaded walks and modern store-buildings. Neat little houses, properly designed for hot weather use, furnish the men and their families comfortable homes, but no praise is too great for the real effort displayed to relieve the terrible desert monotony with a spot which delights the eye.

The officials of the Phelps-Dodge Corporation had more to work upon at Tyrone, New Mexico, than did their competitors at Ajo, yet one has as much admiration of the way they have improved their opportunities. Their settlement is approached by a wonderful roadway over the continental divide, and is situated in attractive rolling hills, covered with scrubby trees and bushes where foliage is almost evergreen. How well their engineers have availed themselves of these advantages is seen from the picture of the Mexican houses built on Bellotal Avenue, which is merely one of the roads winding back through the little valleys converging to the plaza itself. One familiar with the squalor of the ordinary pueblo almost wonders if the Mexican appreciates such advantages as would the Western American.

### War-Profits in Metal Industries.

The Federal Trade Commission has submitted a lengthy report at the request of the Senate, giving their available information on the present range of profits in various industries. In the case of the metal industries, this information is largely gained by cost-finding by the experts in the Commission's employ.

In general, the commission declares that profiteering exists, much of it due to advantage being taken of the necessities of heavy production, but some of it to "inordinate greed and barefaced fraud." Some instances of fictitious padding of cost accounts were found, by such means as large depreciation charges, increased salaries of officials, adding interest to cost, charging new construction to repairs, placing inflated value on raw materials, and manipulation of inventories. The outstanding revelation is the heavy profit made by the low-cost concern working under a price fixed by the government to stimulate production from even the higher-cost institutions. This not only produces an economic situation fraught with hardship to the consuming public, but strengthens the dominating position of the low-cost plants.

In the case of steel, the United States Steel Corporation is cited as an instance of the fully integrated mill; its profits in terms of the total amount invested show net earnings as follows:

|            | Per Cent |
|------------|----------|
| 1912 ..... | 4.7      |
| 1913 ..... | 5.7      |
| 1914 ..... | 2.8      |
| 1915 ..... | 5.2      |
| 1916 ..... | 15.6     |
| 1917 ..... | 24.9     |

Mills which start with steel furnaces are generally very prosperous. In some cases individual mills have made objection that the government prices are too low for them to show returns on investment of from 40 to 319 per cent on the business of 1917.

Figures show that 21 copper companies, including a large proportion of the so-called "high-cost" companies, made 1917 profits of from 1 to 107 per cent, an average of 24.4 per cent, as compared to 11.7 in 1913. Probably over 70 per cent of the production is marketed at profits of over 20 per cent on the investment. There does not appear to have been any concerted action in putting up prices; the high level is attributed to the scramble among the Allied governments for the metal. In this trade, as in others, however, there is a strong tendency to increase and maintain prices against the forces of competition. For instance, custom smelters continue to hold in force deductions for the risk of carrying copper, which risk no longer exists. On the other hand, some large mining companies have long-term contracts still in force which enable them to have their ores smelted at less than present cost.

No unusual profits exist in the zinc industry, taken as a whole, except in the case of the New Jersey Zinc Company, whose position is due to the possession of an ore body of unusual richness and purity. This company published its profits for 1916 as being 72.5 per cent, and they paid dividends amounting to 76 per cent, while the Trade Commission's figures indicate a real profit of 95.9 per cent for that year.

The International Nickel Company has a natural monopoly on nickel in the United States, owing to its ownership of mines in Canada. It has maintained prices at the pre-war level, and its increased profits have been due to increased output demanded by the war. While "profiteering" in this case is not charged, the Commission questions whether the company might not have been satisfied with smaller prices and smaller profits in an essentially war material.

## Program of Fourth National Exposition of Chemical Industries

Grand Central Palace, New York

Week of Sept. 23, 1918

The addresses comprise a series of symposiums devoted to a consideration of

THE DEVELOPMENT OF CHEMICAL INDUSTRIES IN THE UNITED STATES, NOTABLY SINCE JULY, 1914.

Monday, September 23rd.

Afternoon (2:30 P.M.) Opening Addresses.

CHARLES H. HERTY, Chairman, Advisory Committee.

WM. H. NICHOLS, President, American Chemical Society.

F. J. TONE, President, American Electrochemical Society.

G. W. THOMPSON, President, American Institute of Chemical Engineers.

Evening (8 P.M.) Motion Pictures.

WATER POWER, ITS DEVELOPMENT AND USE

\*The Falls of Iguizu, Argentine; Great Latent Powers.

\*Power of Wealth—Hydraulic Development.

\*Power Transmission (4 reels).

Canadian Shawinigan Falls Power Development and Its Surrounding Chemical Industries (3 reels). (Shawinigan Water & Power Co.)

\*Fixation of Atmospheric Nitrogen at Niagara Falls and Feeding the Soil With It (2 reels). (American Cyanamid Co.)

Tuesday, September 24th.

Afternoon (2:30 P.M.) Symposium: ACIDS and CHEMICAL ENGINEERING.

E. J. PRANKE (American Cyanamid Co.), Development of Nitric Acid Manufacture.

EMERSON P. POSTE (Elyria Enameled Products Co.), Developments in the Manufacture of Glass Enameled Apparatus.

Evening (8 P.M.) Motion Pictures.

THE OIL INDUSTRIES

\*The Story of a Cake of Soap.

\*Light from the Rocks; Natural Gas (4 reels).

Lake Asphalt Industry (Barber Asphalt Co.).

Asphalt Roofing Industry (Barber Asphalt Co.).

Asphalt Colloids (Barber Asphalt Co.).

(9 P.M.) Speakers:

J. A. SWITZER (University of Tenn.), Waterpower Potentialities of East Tennessee.

HERBERT C. HENEGAR (American Zinc Co.), Mineral Resources of East Ten-

nessee. (Representing Knoxville Chamber of Commerce.)

### Wednesday, September 25th.

Afternoon (2:30 P.M.) Symposium: POTASH.

C. A. HIGGINS (Hercules Powder Co.), Recovery of Potash from Kelp.

LINN BRADLEY (Research Corporation), Recovery of Potash from Iron Blast Furnaces and Cement Kilns by Electrical Precipitation.

JOHN W. HORNSEY, Potash from Desert Lakes and Alunite.

ALFRED DE ROPP, JR. (American Trona Co.), Potash from Searles Lake.

Evening (8 P.M.) Motion Pictures.

Electrical Precipitation of Potash from Cement Dust (Research Corporation).

\*Colloid Chemistry.

The Operation of a By-Products Coke Plant (2 reels). (H. Koppers Co.)

Moving a Forest to France (4 reels). (Southern Pine Association.)

The Story of Potash—Production at Searles Lake.

### Thursday, September 26th.

Afternoon (2:30 P.M.) Meeting: AMERICAN CERAMIC SOCIETY—Chairman, L. E. Barringer.

L. E. BARRINGER—Manufacture of Electrical Porcelain (Illustrated, Motion Picture).

A. V. BLEININGER—Recent Developments in the Ceramic Industries.

H. RIES—American Clays.

F. A. WHITAKER—Manufacture of Stoneware (Illustrated, Slides).

J. B. SHAW—Fuel Conservation.

S. C. LINBARGER—Carborundum Refractories.

These will be followed by motion pictures as designated for the evening program.

Evening (8 P.M.) Motion Pictures.

#### THE CERAMIC INDUSTRIES

Glass Making (Corning Glass Co.)

†The Making of Cut Glass.

Manufacture of Electrical Porcelain (General Electric Co.).

†The Making of Pottery.

(9 P.M.) Speakers:

J. A. SWITZER (University of Tennessee), Waterpower Potentialities of East Tennessee.

HERBERT C. HENEGAR (American Zinc Co.), Mineral Resources of East Tennessee. (Representing Knoxville Chamber of Commerce.)

### Friday, September 27th.

Afternoon (2:30 P.M.) Symposium: METAL INDUSTRIES.

LEONARD WALDO (Rumford Metal Co.), Development of the Magnesium Industry.

ALCAN HIRSCH (Hirsch Laboratories), Ferro-Cerium Pyrophoric Alloys.

THEODORE SWANN (Southern Manganese Corp.), Ferro-Manganese.

JOS. W. RICHARDS (Lehigh University), Ferro Alloys of Silicon, Tungsten, Uranium, Vanadium, Molybdenum and Titanium.

Evening (8 P.M.) Motion Pictures.

CARELESSNESS: THE DESTRUCTION OF LIFE, WEALTH AND RESOURCES

Careless America (Firestone-Universal).

\*The Crime of Carelessness.

\*The Workman's Lesson.

Keep Your Business Going (3 reels). (General Fire Extinguisher Co.)

\*Vaccines for Prevention of Disease (4 reels).

### Saturday, September 28th.

Afternoon (2:30 P.M.) Symposium: INDUSTRIAL ORGANIC CHEMISTRY.

S. P. SADTLER (S. P. Sadtler & Son), Industrial Organic Chemistry and Its Progress.

C. A. HIGGINS (Hercules Powder Co.), Kelp as a Source of Organic Solvents.

GEO. H. TOMLINSON (Kinzing, Bruce & Co., Inc.), Wood as a Source of Ethyl Alcohol.

Evening (7 P.M.) Motion Pictures.

Manufacture of Zinc Oxide (New Jersey Zinc Co.).

Manufacture of Genuine Wrought Iron Pipe (3 reels). (A. M. Byers Co.)

\*From Log to Lumber (4 reels). (Southern Pine Association)

The Wonderland of the Appalachians (3 reels). (Cinchfield Railway)

From Coal Mine to Corn Field—Production and Use of Ammonium Sulphate (The Barrett Co.).

(9 P.M.) Speakers:

J. A. SWITZER (University of Tennessee), Waterpower Potentialities of East Tennessee.

HERBERT C. HENEGAR (American Zinc Co.), Mineral Resources of East Tennessee. (Representing Knoxville Chamber of Commerce.)

### Synthetic Phenol

Our attention has been directed to an error which occurred in the make-up of the article of Mr. A. G. Peterkin in our issue for September 1, 1918. The titles of Charts I and II were inadvertently reversed and should be changed in order to make the descriptions clear. Chart I represents the new process of Dennis and Bull, and Chart II the old Barrett process. If the titles are transposed the references in the text will be correct and no further confusion will follow.

\*Films so indicated are shown by courtesy of Bureau of Commercial Economics.

†Films so indicated are shown by courtesy of Ford Motor Co. Films are all single reel unless otherwise indicated.

## Colorado Meeting of the American Institute of Mining Engineers

An Account of the Technical Sessions Held at Denver and Colorado Springs—Members of the Institute Visit Mines and Metallurgical Plants at Denver, Colorado Springs, Cripple Creek, Pueblo and Leadville

THE one hundred seventeenth meeting of the American Institute of Mining Engineers, held in Colorado during the week of September 2, was the first to be held in the Centennial State for twenty-two years. The meeting was a pronounced success, worthy of Colorado engineers and comparing favorably with the Institute's Western meetings in recent years. All this was in spite of the bad weather which pursued the convention almost throughout the week, culminating on Thursday in a heavy snowstorm which almost stalled the party in its Pike's Peak automobile trip, and prevented the visit to the Golden Cycle mill.

### MONDAY, SEPTEMBER 2

The meeting opened on Monday, September 2, with a technical session on Metallurgy, held in the Brown Palace Hotel in Denver. There was a large attendance of engineers, but unfortunately very little discussion of the papers developed. In the absence of the authors, all of the contributions except that by C. A. HANSEN were read by title. The paper on Electrostatic Precipitation by O. H. ESCHHOLZ brought forth a large amount of written discussion, while so many members present asked for rather extended time in which to present their views that the chairman of the meeting, Mr. T. B. STEARNS, announced that a special session on precipitation would be held later in the week. Discussion of this paper was therefore deferred until Thursday evening at Colorado Springs, and is reported farther on.

Immediately after adjournment, the members and guests were taken to the ferro-alloy plants near Utah Junction, the equipment of which was described in a paper at the morning session by ROBERT M. KEENEY, manager of the Iron Mountain Alloy Co.

### Visit to Ferro-Alloy Plants

The plant of the Iron Mountain Alloy Co. contains one 1200-kw., three-phase furnace, and one 1800-kw., three-phase furnace, giving a total capacity of 12 long tons of ferromanganese per 24 hours. The former furnace is supplied with power by three 400-kw., single-phase transformers, having a ratio of 13,200 to 75 volts, and connected  $\Delta/\Delta$ . The voltage on the furnace is 72 volts. The 1800-kw. furnace is likewise connected to three 600-kw., single-phase transformers. The furnace shells in both cases are 18 ft. long, 8 ft. wide, 7 ft. deep, and are lined with magnesite. The electrodes on the smaller furnace are of carbon, 17 in. in diameter, and on the large furnace 24 in. in diameter. No roofs are used, and regulation of electrodes is by hand.

The plant of the Ferro Alloy Co., also at Utah Junction, contains one 750-kw., three-phase furnace, to which power is supplied by three 250-kw. transformers, connected  $\Delta/\gamma$  to give 129 volts on the furnace cables, the transformer ratio being 13,200 to 75 volts. The furnace operates with an actual voltage of 120 volts, and produces about 3 tons of ferrochrome per 24 hr. from 40 per cent  $\text{Cr}_2\text{O}_3$  ore. The furnace consists of a steel shell of circular cross-section, 8 ft. in diameter by 7 ft. deep, lined with magnesite, and having three 12-in. carbon electrodes. A 450-kw. furnace, of the same size as the 750-kw. furnace, is also operated on chrome ore. This furnace is three-phase in appearance, but operates electrically as a single-phase furnace. There are three vertical carbon electrodes 8 in. in diameter with a conducting carbon bottom. Power is supplied by three 150-kw., single-phase transformers, two of which have a ratio of 13,200 to 95 volts, and one a ratio of 13,200 to 100 volts. From each transformer, one lead goes to one vertical electrode, and one lead to the carbon bottom,

so that the transformers are electrically independent. The furnace voltage varies from 90 to 95 volts.

At intervals, 150-kw., single-phase furnaces are operated on ferrotungsten. These furnaces have one vertical graphite electrode 4 in. in diameter, with a water-cooled steel bottom-contact. The furnace shells are 4 ft. in diameter, and are mounted on trunnions, the slag being poured by tilting the furnace. All of the electrodes are regulated by hand. The chrome furnaces are operated without roofs and the tungsten furnaces with roofs.

#### Tour of Mountain Parks

After the excursion to the electric-furnace plants, and luncheon at the Denver Club, came the incomparable automobile ride over Genessee Mountain through Denver's mountain parks. Many stopped en route at the pottery of the Herold Porcelain Works in Golden. This most pleasant day closed with an informal dinner at the country club.

#### Oxygen and Sulphur in the Melting of Copper Cathodes

At the morning session on metallurgical subjects, STANISLAUS SKOWRONSKI, research engineer of the Rariton Copper Works, presented two papers on the furnace refining of copper cathodes.

Discussing his first paper, the author gave the results of analyses of samples of copper taken from a refining furnace at 30-minute intervals when poling under both a coke and charcoal cover. The results are presented in graphical form and show that in the oxidation period the reversible reaction

starts toward the right immediately and is completed when the oxygen content of the charge is about 0.35 per cent. It apparently reverses when poling has brought the oxygen down to about 0.08 per cent. The sulphur in cast copper is mostly absorbed from the carbonaceous cover; therefore charcoal gives a lower-sulphur copper than does coke.

It is becoming better understood that the "surface set" on the pitch of copper is directly controlled by the sulphur and perhaps certain reducing gases, such as carbon monoxide and hydrogen, rather than by the oxygen; that sulphur raises the "set" or overpoles the copper, thus necessitating a certain amount of oxygen which therefore depresses the "set" to counterbalance the action of the sulphur.

In these two charges sampled, the "pitch" of the copper was the same, yet owing to the lower sulphur in the product melted under charcoal, its oxygen content is also much lower, affording great improvement in the quality of the copper. The refiner did not know how much sulphur was present in his final product; he simply worked the copper to the desired pitch, and the sulphur present in each charge determined the amount of oxygen necessary to give the proper "surface set" on the copper.

#### Relation of Sulphur to Overpoling of Copper

In Mr. SKOWRONSKI's second paper, the common definition of overpoling was advanced; that is "copper which has been excessively reduced during the poling period of the refining process" and so porous as to

be unfit for use. When melting very pure cathode copper in a graphite crucible under charcoal and in contact with green wood, the resulting ingots (free of sulphur and very low in oxygen) had a "level" set and proper "pitch." Overpoling is therefore thought not due to a lack of oxygen—it is apparently impossible to overpole copper by over-reduction if it does not contain sulphur and possibly other reducing gases. High-sulphur alloys were made by melting cathode chips with the addition of weighed amounts of cuprous sulphide. When melted in uncovered crucible, the oxygen tended to increase with the sulphur, thus giving in most cases no evidences of overpoling. When melted under charcoal, however, the oxygen was reduced approximately 75 per cent and the high-sulphur ingots were badly overpoled. Another study of the electrical characteristics of copper ingots showed that a low conductivity was due to oxygen rather than sulphur.

From these results, it is evident that cuprous oxide counteracts the effect of sulphur, either by increasing the solubility of sulphur in copper, or, as pointed out by Johnson, by inducing a physical condition of equilibrium between the sulphur, tending to "overpole" the copper, and the cuprous oxide, tending to "underpole" it. Yet neither theory explains the fact that when a charge of copper is "overpoled" it cannot be righted by a simple addition of cuprous oxide, but the charge must be re-worked to set copper.

"It takes a comparatively large amount of cuprous oxide to counteract a trace of sulphur; this explains why, in the refining of copper, the gases from fresh fuel will often "overpole" the copper during the casting period, and also why copper cannot be held in the furnace at the proper pitch more than a few hours. It also explains the limit of recharging cathode sheets into the furnace after the copper has been worked to the proper pitch, the sulphate present on the cathode sheets overbalancing the equilibrium established between the cuprous oxide and the sulphur."

The author concludes that both oxygen and sulphur affect the pitch of the copper, leaving open the questionable effect of hydrogen and carbon monoxide.

Discussing this paper Mr. PHILIP L. GILL pointed out the difficulty of maintaining a balance between cuprous oxide and the reducing gases when casting conditions are favorable to segregation, and he thought that many experimental results could be ascribed to the fact that copper cast in small chills set differently than in large wire-bars. He was always able to overpole copper in refining furnaces, even when melting sulphur-free cathodes with low-sulphur coal and when poling under charcoal. In such cases of overpoling a 100,000-lb. bath, the copper absorbed at least 20 pounds of something in 20 minutes, this something he thought more likely to be carbon monoxide and hydrogen from the green wood than the  $\text{SO}_2$  from the furnace gases.

#### Electrolytic Zinc

An important paper by C. A. HANSEN on this subject has already been abstracted in METALLURGICAL AND CHEMICAL ENGINEERING, May 1, 1918, Vol. 18, p. 481. Mr. J. L. VARDLEY thought that a more timely publica-

tion of such important information would have prevented the duplication of much tedious research. Also that since at the present time there are three very large plants operating on three widely different ores by processes independently and simultaneously perfected, the electrolytic production of zinc was evidently not such an abstruse problem as published information would lead one to believe.

Replying to a query, Mr. Hansen stated that he was absolutely sure that the Tainton or any other process operating at a high current density and acidity must have a substantially pure electrolyte in order to deposit zinc successfully.

### Antimony Smelting in China

CHUNG YU WANG presented notes supplementary to his book on Antimony, showing drawings and photographs of various types of furnaces in use in the different Chinese smelters, and detailed information on furnace charges and operation. The author notes that under the stimulus of the war price of \$900 (Mexican) per ton of regulus, a number of small smelters were erected so that the total capacity of 23,000 tons per year is now in existence. He presents two detailed cost sheets showing that the pre-war cost of \$63 per ton of regulus (1911) had jumped to \$180 in 1915.

"Due to the lack of capital, and of mutual coördination and coöperation among the smelters and the shortsighted policy of the directors of the different companies, there has not been any marked progress in the metallurgy of antimony in China. Obviously an important line of future progress should be in the direction of eliminating the heavy losses due to volatilization of the metal during the successive steps of treatment. If the loss could be lowered from the present 20 per cent to 10 per cent, or possibly less, an annual saving of at least \$600,000 would be effected, which would more than pay back the capital outlay for such alterations and additions to the existing plants."

Mr. Wang also advocates the substitution of a mechanical roaster for the long reverberatories now in use to oxidize the crude or rich ore, the improvement of the liquation furnaces, the adoption of gas-firing, and the installation of Cottrell plants. Discussing the use of "*couverture*," the author notes the well-known fact that the "market always demands good stars with fern-like structure on the slab of regulus before its acceptance. The appearance of such structure does not actually indicate the relative purity of the regulus, but is only the result of cooling it under the cover of a properly prepared starring mixture—in the absence of a proper English term, I shall call it by its French equivalent *couverture*—whose fusion point is lower than that of antimony, which is 620 deg. C. Of course, when the regulus contains impurities like sulphur, arsenic, lead or iron to any appreciable quantity, its surface shows it by specks, by a leaden appearance or by an ill-defined appearance of the fern-like structure. On the other hand, I have seen many a slab of regulus, with impurities above what are considered to be the limits imposed by buyers, whose stars are still bright and well-defined with all the appearance of well refined regulus. Now since the buyer demands such unnecessary adornment on the regulus,

he has to pay for it; for the costs for starring 1 ton of regulus amount to from \$10 to \$60 (Mexican), according to the market price of the antimony compound used. The proper procedure for charging any of the above mixtures is as follows: The mixed *couverture* compounds (usually antimony tioxate plus-soda or potash), are immediately charged into the reduction furnace as soon as the skimming is finished. The doors are closed and vigorous firing is maintained; as soon as it is observed that the mixture is completely melted, ladling commences. Each ladle dips into the molten metal and, in coming out, picks up a certain quantity of the molten *couverture*, which, when poured out rapidly together with the metal into a hot mold, completely covers the metal on all sides." The thickness of the solidified *couverture* varies from 1 to 2 mm. on all sides, 5 to 7 mm. on top, and varies from  $\frac{1}{3}$  to  $\frac{1}{4}$  the weight of the regulus produced. About  $\frac{1}{3}$  of the compound is lost by volatilization and by wall-fluxing; it is hammered from the slab and re-used until it becomes foul, when it is resmelted.

### Metallography of Tungsten

This subject was discussed at length in a scholarly paper by ZAY JEFFRIES. After briefly reviewing the manufacture of wrought tungsten products, the author discusses at considerable length the relation between thoria contents, temperature and grain-growth as explained by the germinative temperature laws. This subject is of importance in the manufacture and life of lamp filaments. For instance, an ingot made of very fine metallic powder welded at the minimum temperature is too fine grained, brittle and hard to be worked. By heating this ingot just above the germinative temperature the ingots are much more readily deformed. On the other hand it is desirable to keep the grain size as small as possible since the resistance to grain growth inherent in the small size gives better results in the lamp filament, for the operating temperatures in an incandescent lamp are in the grain-growth range.

"Tungsten is not an easy metal to polish. It is so resistant to the action of abrasion of the polishing powders that levigated alumina can be substituted for tripoli to advantage just preceding the rouge.

"White cast iron has been used to advantage as a mounting material for small pieces of tungsten which cannot conveniently be handled without some sort of a mounting. The piece of tungsten to be mounted is put in a mold and the molten cast iron poured around it. The white cast iron and tungsten are so nearly the same hardness that flat surfaces can be produced on the tungsten during polishing. It is sometimes very difficult to mount and polish the smallest tungsten wires. This has been accomplished in a successful manner, however, on wires less than 0.001 in. in diameter. One satisfactory method is as follows: An ordinary malleable iron  $\frac{3}{8}$ -in. (9.5-mm.) pipe cap is planed on the closed end outside. It is then drilled on the inside to a plane parallel to the outside plane. A round cover glass is put on the inside of the pipe cap, on which are placed several pieces of the small tungsten wire to be polished. Another cover glass is placed on top of these wires, after which the opening of the pipe cap is filled with powdered glass. It is then put in a furnace, being maintained in an upright

position, and heated for about 5 min. to a temperature of 800 or 900 deg. C. It has been found in many experiments that this temperature does not affect the structure of tungsten wire. The pipe cap with contents is then removed from the furnace and the glass which has congealed is pressed tightly into the pipe cap and allowed to cool slowly. The metal portion on the end of the pipe cap is then turned off in a lathe and the glass is exposed. This glass containing the samples of tungsten is polished in the ordinary manner until the tungsten wires are exposed, and the polishing is completed in the ordinary manner.

"Boiling hydrogen peroxide is used for etching most of the tungsten products. Tungsten may also be etched electrolytically with good results, using a solution of sodium hydrate for electrolyte."

Tungsten is particularly distinguished because it is brittle at room temperature when composed of small equiaxed grains, yet when of fibrous structure it is ductile and pliable. Commonly metals act exactly oppositely. Mr. Jeffries explains this phenomenon by a careful consideration of the variation in plasticity and cohesiveness of the crystalline particles and the amorphous cement binding them together. At room temperatures the somewhat malleable grains cannot deform to any considerable extent before failure occurs through the amorphous cement. In fibrous tungsten, on the other hand, the grain distortion has so arranged the boundaries that rupture is forced to take the shorter path through the more ductile grains, even though a larger absolute amount of amorphous material is then present.

Prof. C. H. FULTON, of Case School of Applied Science, presented a noteworthy paper on "The Condensation of Zinc from Its Vapor," which we will publish in full in a later issue.

#### Manufacture of Ferro-Alloys in the Electric Furnace

ROBERT M. KEENEY presented a lengthy account of the manufacture of the ferro-alloys of chromium, manganese, molybdenum, tungsten, and vanadium, giving in tabular form furnace sheets of a great many charges. This part of the contribution is so packed with information that justice cannot be rendered in an abstract, and those interested in these alloys will refer to the original.

The latter half of the paper gives the results of many experiments on ferro-uranium, the records of his failures being no less valuable than of his successes.

"Ferro-uranium was developed not because of any particular need for uranium in steel manufacture, but because of the large quantity of sodium uranate,  $\text{Na}_2\text{U}_2\text{O}_7$ , that was accumulating as a by-product of radium production. At the start, uranium exhibited one of its fundamental characteristics, its strong affinity for carbon and its tendency to form carbides. Also, in this early work it was found that no fluxing material except fluorspar could be used with sodium uranate; if either lime or silica was added, the uranium remained in the slag with practically no reduction, thus exhibiting its second characteristic, its strong affinity for oxygen."

In the attempt to make a 20 per cent uranium alloy, steel turnings were melted, and then a mixture of sodium uranate, coke and fluorspar added. It was found

that until there is 0.4 lb. of carbon in the charge for every pound of uranium very little reduction occurs. From 0.4 to 0.7 lb. carbon the percentage of uranium in the alloy varies little and the percentage of carbon in the alloy remains between 3.5 and 4.0 per cent. Both analytical and microscopic examinations indicated that when there was enough carbon present to form the double carbide,  $\text{Fe}_2\text{C}\cdot\text{U}_2\text{C}$ , the ferro-uranium held the uranium, and only then. Since the carbon in the alloy was considered excessive, decarbonization with iron scale alone and with silica was unsuccessfully attempted, for the reason that the tendency to form iron uranate results in slogging all the uranium. Melting with  $\text{U}_3\text{O}_8$  was equally a failure. Neither can ferro-uranium be made using silicon as a reducer with a commercial recovery or a low-silicon alloy.

Since satisfactory low uranium alloys were not forthcoming, attempts to produce the pure metal were made. Unsuccessful attempts resulted with sodium, carbon, aluminium and silicon in a gas furnace, but in a stationary Siemens electric furnace with magnesite walls and carbon bottom "uranium metal was reduced by carbon to a button containing over 90 per cent uranium and from 3.5 to 4 per cent carbon. The production of this low-carbon metal, with the minimum amount of carbon charged, depends entirely on manipulation of the electric furnace, a very high temperature being necessary. The product is an alloy of uranium carbide and uranium metal. The silicon and iron can be kept at about 1.5 per cent each, and the vanadium at 1.25 per cent, with the oxide used. The uranium recovery in a single operation will be from 50 to 60 per cent. The material left in the furnace is a mixture of pure oxide and carbon, which can be charged again as soon as its carbon content is determined. In this way, the ultimate recovery of uranium is high, well over 85 per cent. The power consumption is high, because pure uranium oxide is being reduced. It averages about 8 kw.-hr. per pound of metal." Two per cent carbon or more is necessary in the final product in order that all the uranium oxide be reduced, while if the button of hot sponge-metal is removed from the furnace it immediately oxidizes.

"To secure the proper temperature, the furnace must arc all the time. Regular charging is necessary. The uranium metal is allowed to form a sponge on the bottom of the furnace, which gradually builds up. Directly beneath the electrode, this sponge is pasty, but not fluid. The charge forms its own furnace lining. When a run is finished, the button of uranium metal is removed from the furnace. The unreduced residue is re-treated with another charge," giving practically complete recovery. The button contains 4.4 per cent carbon, 1.4 per cent silicon, 1.4 per cent iron, 1.3 per cent vanadium.

Given a low-carbon metal the next problem was to add it to molten steel in such a manner that its uniform incorporation would ensue. Experimenting with molten steel in an electric furnace, it was found that uranium metal was not a good addition agent because it must be in the steel bath for a considerable time to melt, while it oxidizes and slags nearly as rapidly as it becomes molten. With the experience already gained it was
